Upon the preliminary question, whether over-pressure does exist at the present moment, the opinion of the great majority of the witnesses was unmistakably that the fact is so. Out of forty-two who were interrogated on the point, twenty-six said distinctly "Yes," eleven said more or less distinctly "No," and five answered equivocally. Upon the whole, therefore, there was a strong preponderance of opinion in favour of the affirmative view, and in fact the set of opinion was even more distinctly in this direction than this mere summary analysis would indicate. For in most cases "No" meant only that instances of over-pressure had not come under the witness's own observation, and they do not in the least, therefore, conflict with the "Yes" of other witnesses whose less happy experience had made them acquainted with over-pressure, occasionally in very grievous measure. It never, of course, has been suggested that over-pressure existed in every school, and it is only necessary to recall the guarded language used by Sir J. CRICHTON BROWNE in 1885 to perceive that the net result of the opinions now collected is to establish to the letter what he then said. His conclusion was that "46 per cent. of the children attending elementary schools in the poorer districts of London suffer at certain seasons from habitual headache," in part attributable to over-pressure in the course of their education. No doubt the public attention was largely directed, in the discussion which ensued, upon those extreme cases in which nervous disorders, originated or promoted by the strain of education, had resulted actually in death. But these cases are obviously exceptional. The mischief, more serious in the aggregate than these occasional instances of entire collapse, against which it is especially necessary for the directors of juvenile education to be upon their guard is manifested rather by the slighter ailments, which are conveniently grouped under the symptom of habitual headache.

The evil having been thus clearly indicated, it might have been expected, perhaps, that the Commissioners would be careful to make a large collection of facts, from which any competent person might draw his own conclusions. This, however, they have, strangely enough, entirely failed to do. In view of the remarkable deficiencies of the report in this respect, we can but regret that no medical man was included in the Commission. As matters stood, there does not seem to have been anybody engaged about the inquiry who could indicate to the witnesses what were the specific points and special symptoms to which they might most usefully speak. The question was generally put in some such form as this: "Do you think there is any over-pressure in such and such a school?" It is obvious that the answer to such a question would depend quite as much on the witness as on the facts. The inquiry, as we think, should have been conducted in a wholly different manner. Questions suggested by medical experience would no doubt have revealed the fact that many of the ladies and gentlemen who expressed to the Commissioners very decided opinions had no adequate foundation for their views, and, on the other hand, they would have elicited a large body of facts which are to this moment undisclosed. How large and how valuable these facts would have been, if only the Commissioners had known how to set about collecting them, may be gathered from one or two observations which fell in the course of the inquiry from some exceptionally clear-headed and well-informed witnesses. One gentleman, for instance, a manager of a village school in Sussex, found occasion, when replying to the question "How do you define 'over-pressure?'" to observe "Before every examination I hear complaints from parents of children talking in their sleep, or that they cannot sleep, or that they walk in their sleep ..... but then I must say that in my own school the children are all excessively anxious individually to pass; they take a very desperate interest in it, and it is considered a direful disgrace to the whole family if they make a failure, and they never hear the last of it." Another, the vicar of Isleworth, said: "I saw a new form of it [over-pressure] the other day. I heard of some girls who did not come in the afternoon because they were so pressed in the morning..... Their parents ..... have been in in the habit, when their children came home tired after morning work, of keeping them away from school in the afternoon.' Even in these instances the inquiry was not followed up, and the witnesses were not asked to indicate the actual or proportional number of the children to whom their remarks applied. This is much to be regretted; yet, imperfect as they are, a handful of such facts is worth a houseful of generalised statements and mere expressions of opinion. We are sorry to add that it is to this latter category that almost the whole of the evidence in this branch of their inquiry collected by the Royal Commissioners must be referred.

Upon the whole, then, the report of the Royal Commission is a distinctly disappointing document. Much very valuable matter has no doubt been put together, but upon the important question in which the medical profession is chiefly interested the result attained is almost a cipher, and the feeling forces itself upon us that a splendid opportunity of

Digitized by Google

collecting facts has been sadly wasted, for want, not of will, but of scientific qualifications on the part of the Commissioners engaged in the inquiry.

WE have on two recent occasions drawn attention to the question of the spread of infection through the agency of rags, and we have now before us a further report from the medical department of the Local Government Board, in which the occasion of a small-pox prevalence in connexion with some paper-mills at Ivybridge in South Devon is taken to deal in a somewhat exhaustive manner with the whole subject and with its treatment in this and in foreign countries. We do not propose to discuss that portion of Dr. PARSONS' report which deals with this special small-pox occurrence; but as regards general considerations as to rag infection at paper-mills, we may state that although cases of infection by means of rags do occasionally occur, yet they are, considering all the circumstances, only of infrequent occurrence. This infrequency is to some extent due to the fact that it is essentially the white rags, from which the finer class of paper is made, that are most risky, because they have formed articles of underclothing, &c., which come into actual contact with the bodies of persons. The great body of rags are coloured ones, and with these the amount of manipulation needed is much less than with those required for the superior class of manufacture. Then, again, in this country at least, the 120th section of the Public Health Act does deter people to some extent from trafficking in rags known to be infected; and, apart from the law as to the matter, a large number of people take certain precautions in their dealings with rags which have run the risk of being infected. Rags before reaching paper-mills have also been several times sorted and exposed, and it is often some months before they reach the cutter's hands. And, lastly, it is only those who are engaged in dealing with rags during the preliminary stages of the manufacture that run much risk; the boiling and chemical treatment to which rags are submitted after cutting must practically render them innocuous.

Reviewing all the available precautions against infection by means of rags, Dr. PARSONS lays down the following rules. Against small-pox, vaccination and revaccination should, in the main, be trusted to. Since infection doubtless takes place mostly as the result of inhalation of "dust" during the processes of manipulation and cutting, such dust often consisting of matters which have dried into and on the surface of the rags, ventilation is an important consideration, and fans to draw off the dust would be eminently useful. Where it is known that disease prevails in a locality, rags from that place should, if possible, be prohibited from importation. This is done in the case of cholera, but it is hardly practicable with our current infectious fevers. Finally, disinfection of rags should be aimed at. The processes that seem at all applicable are: (1) Chemical disinfection by gases, as sulphurous acid or chlorine; but unfortunately the gases would not penetrate bundles or heaps of rags. (2) Disinfection by heat, especially in the form of steam. This latter system works well, and a report made to Dr. SMITH of New York is quoted as to the opinion of an experienced rag inspector, to the effect that the market value of the rags is in no way impaired by the process. The difficulty of dealing with rags by disinfection is to determine who is to bear the expense of it. The original responsibility rests on either the person who sells the rags, or the rag merchant, who buys them regardless of the source whence they come; and, as Dr. PARSONS says, it would hardly seem fair to require paper manufacturers to atone for the omission of others by a comparatively expensive process of disinfection. The question may be raised in future sanitary legislation, and it may be that the public authorities will, in the interest of the communities they represent, themselves undertake the task of disinfecting such articles as rags. One of the most valuable parts of Dr. PARSONS' report is contained in a series of Appendices giving a summary of the principal outbreaks at paper mills, and an abstract of information obtained through the Foreign Office as to the measures taken in a large number of foreign countries with regard to this question of rag infection. For these reasons alone we are glad to see that the report is placed on sale.[1]

No less than four Bills having for their ostensible object the repression of adulteration are now before Parliament. For the purpose of scientific argument these Bills may, however, be reduced to two, of which one deals with beer and one with butter. There are, it is true, two similar Beer Bills and two similar Butter Bills, but in each case the differences are of minor importance. In the Beer Bills a definition is attempted which would render the punishment of adulteration a simple matter if the offence were proved. Adulterated beer is "any beer brewed from or containing any ingredients other than hops or ["and" in one of the Bills] malt from barley." If any other ingredients are used by the brewer or publican, "conspicuous notice" must be given to the public in the bar or other place where the beer is sold or offered for sale. This is simple enough, and would evidently prohibit the sale without special description of all beer in which sugar, rice, or maize had been used instead of, or in addition to, malt; or any hop substitute, such as quassia, instead of, or in addition to, hops. This somewhat pedantic phraseology is essential to a comprehension of the difficulties with which the question is surrounded.

In the other Bills which propose to deal with butter, a definition which in this case is attended with less difficulty is enunciated. The definition differs slightly in the two Bills, but, taking the wider and more sensible, it is "the substance usually known as butter, made exclusively from milk or cream, or both, with common salt, and with or without additional colouring matter." The only adulterant named or aimed at in either of the Bills is margarine or oleomargarine, which in the better drawn of the two Bills is defined to include "all substances, whether compounds or otherwise, prepared in imitation of butter, and whether mixed with butter or not." The Bill in either form would require considerable revision before it could pass into law, but, as its objects are simple and easily attainable, it may for the moment be postponed, although it will be necessary to discuss it at a later stage.

With these important proposals before Parliament, it is not surprising that the small but vigorous Society of Public

Analysts, which includes among its members nearly all the best public analysts of Great Britain, should have taken prompt action and summoned a conference to consider the general questions involved. The meeting on May 11th was, in fact, a conference. Several letters from absent members and some original papers were read, and a good discussion took place, which turned almost exclusively upon the use and detection of hop substitutes. The only notable exception was the side issue raised by Mr. OTTO HEHNER as to the relative positions which public analysts and the Government chemists of Somerset House would occupy if any of the new Bills passed into law. It is well known that ever since the passing of the Food and Drugs Act, 1875, some jealousy of the powers then entrusted to the Somerset House chemists has existed among the public analysts, who have fancied themselves slighted by the appointment of an independent court of inquiry. Repeated complaints, sometimes couched in language of unnecessary acrimony, have been made of the conduct of the Government chemists, and in a recent letter to an evening contemporary, Mr. ALLEN of Sheffield, an able chemist who holds the position of President of the Society of Public Analysts, has brought charges against the official chemists which are, in part at any rate, charges of incompetency. To us as to the public, the question is one of subordinate importance. Provided that adulteration is exposed and properly punished, we care very little whether the work is done by the officers of a public department or by analysts appointed by local authorities. On the whole, we should, if suitable modifications were introduced, prefer the present system, because we believe it might easily be made efficient and satisfactory. No one can assert that it is just now either the one or the other. The Government chemists laid it down as their line of duty that they would never certify that a sample was adulterated unless their own analyses proved the adulteration. To that line they have most properly adhered. Doubtless they have made mistakes at times, but we do not think they have ever caused the punishment of an innocent man; and it surely cannot be denied that in the investigation of a charge of fraud the accused ought to be held to be innocent until he is proved to be guilty. In regard to this matter some of Mr. ALLEN'S complaints seem somewhat unreasonable. Thus, speaking of cases of doubt, he says, "If they cannot speak with certainty, they might speak of probabilities." We can but ask what would be the use of that? Fancy a toxicologist employed to test for arsenic reporting that he could not find the poison, but that probably it might be there!

We may now consider the proposed alterations of the law in regard to beer. It must be premised that some very important alterations have already been effected by the Customs and Inland Revenue Act of 1885, which is worked by the Inland Revenue Department. This Act is in some respects extremely vague, and is apparently intended, as so many others have been, mainly for the protection of the revenue. Its definition of beer is about as loose as possible. Beer is a liquor "which is made or sold as a description of beer, or as a substitute for beer, and which on analysis of a sample thereof shall be found to contain more than 2 per cent. of proof spirit." It would seem as though adulteration after such a definition was an almost impossible offence—except, of course, adulteration with noxious ingredients,—and yet the Act specifically and by name prohibits adulteration, and many convictions have already been obtained under it. As Mr. HEHNER puts it, "beer, as permitted to be brewed, is a nondescript article, of no particular composition and of no particular strength." And yet its adulteration is made a penal matter, and it has even been held to be an offence to blend one kind of beer with another, an operation which is practised every day with whiskies. No doubt the law is intelligible to the lawyer, but to the layman it is certainly puzzling.

In strong contrast with the vagueness of the Act of 1885 stand the Beer Bills now before Parliament, the hard and simple definitions of which we have already noticed. The liquor brewed with hops and malt from barley only is in these Bills defined to be pure beer. No other beer is genuine. It may, indeed, be sold, but only with a sufficient warning to the purchaser. This last proviso is tantamount to an admission that beer may be innocuous although other ingredients than barley-malt and hops have been used in its manufacture, for surely no one would propose to legalise the sale under any conditions of a noxious beverage. Looking closely into the matter, we think it cannot be denied that the cry for pure beer is mainly a political cry. It is not pretended that malt substitutes or hop substitutes are necessarily or even commonly injurious to health. Other grains besides barley can be added to malt in brewing: notably rice, which, as it contains less nitrogen, often improves the beer. Glucose also, which is, after all, but an altered form of starch, may, when of good quality, be safely added to the wort before fermentation. So with the hop substitutes. It was stated by all speakers at the recent conference that quassia, gentian, chamomile, and chiretta were not inferior to hop as vegetable bitters. Why, then, should these substitutes for malt or hops be prohibited? It is admitted that they are harmless; the fact that they are used shows that they are cheap; and as for the flavour, the public is the best judge of that. The beer-drinker who wants "pure beer" can always ask for some well-known brand. If he gets an inferior article he is defrauded; the fraud should be severely punished, and doubtless the great brewers would be willing enough to help the purchaser. But if he simply asks for a glass of ale, it is enough that he should be protected from drinking a noxious beverage. If he does not like it he must go somewhere else. Many branches of this important subject still require discussion, but they must be reserved for a future article.

THE Council of the Royal Agricultural Society had last week under discussion Professor AXE'S report on a disease in cows in its relation to the scarlatina epidemic in the north-west district of London, and it was resolved to address a letter to the Privy Council, asking that the Agricultural Department "should undertake further investigations into the subject, with a view to making it clear whether it was possible that scarlatina could, as alleged, be communicated direct from the milk of diseased cows." The President, Lord EGERTON of Tatton, suggested that efforts should be made to determine whether the cow could suffer from scarlet fever; and Mr. COPE, veterinary inspector of the Agricultural Department, after referring to the evidence Dr. KLEIN and Professor AXE had adduced, stated that when an opportunity was afforded by an outbreak of "this

Digitized by Google

eruptive disease appearing among the cows of this country," the Agricultural Department had instructions from the Government to make any inquiries that might be necessary. In the report of the proceedings we note the words "this disease," as if it were an assured fact that the assumption that the Hendon cows suffered from the same malady as certain other herds, the milk of which did not give scarlet fever was correct. It deserves to be borne in mind that Professor AXE, after visiting the Hendon cows, addressed a letter to the British Dairy Farmers' Association, in which he stated that at the time of his visit nothing of the disease remained but a few scabs and superficial ulcers on the teats to mark its former presence; he was therefore "quite unable to say what may have been its precise nature." We refer to this because there are certainly several vesicular diseases of the udder of the cow which do not appear to be sufficiently differentiated, and if the Agricultural Department are guided in their selection of the malady they propose to study by the description Professor AXE has published of a disease the precise nature of which is unknown to him, they will not improbably fall into serious error, which in its results would be disastrous to human life. If the Agricultural Department make it their business to study the natural history of all vesicular diseases which affect the udder of the cow, they will undertake a valuable piece of work, and one which would not be less useful to the agriculturist than to the milk consumer. A lesson to be learnt from recent investigations is the need for the further study of some animal diseases in the interests of the public health, and for this purpose the staff of the Local Government Board should be strengthened by the addition of a skilled veterinary surgeon, and the Board would be doing good service in undertaking the clinical study of these maladies.

THE name of the month of June in the year of Her Majesty's Jubilee sounds sweet, and we are glad to think that it even more than usually suggests many facts which tend to make the human mind less careworn and more happy. Some great sicknesses have gone out of human knowledge. We know them only as we know stage coaches, and not so well. Others have become less terrible. A case of typhus was received into a great hospital in the centre of London a few months ago, and it was referred to and treated as a rarity. The Registrar-General has been telling us that in only one week out of the last five weeks has there been a death from small-pox in London, and that in twenty-five or more out of twenty-eight of the big towns there has not been one such death. The disease is so completely under human control that some thoughtless people have come to disparage the very discovery which protects them. These are very significant facts. But let nobody imagine that our Hospitals are a superfluity yet. The millennium has not arrived. The condition of the people will have to be very different from what it is before hospitals can be dispensed with. Disease still counts for much in the life of the working classes. Defective food, inadequate clothing, mental and physical depression from want of work, poor and insanitary homes, create much and many kinds of sickness which it is hopeless to relieve at home. In addition to this, there are the accidents which befall working men in larger proportion than in other classes—fractures, burns, sprains, herniæ, wounds,—for the treatment of which there is simply no convenience in a poor man's house. Let any of the comfortable classes remember what grave sickness has meant in their experience or in that of their relatives: the best advice, a variety of opinions—all of them of the best,—a skilled nurse, choice and convenient food, and, when the worst was over and hope again in the ascendant, a reviving holiday at the seaside or the country. Such amenities deprive even sickness of half its terrors. The human mind in its divine moods has devised an institution which goes far to put such amenities within the reach of the poorest. The institution in question is no other than a Hospital, where poverty and sickness are the only conditions of entrance, and where the latest discoveries of medicine and the last improvements in nursing, food, and appliances can be had, and in some cases the patient can be passed on even to a convalescent home. This is the very crown of charities, which no civilisation yet reached supersedes, and for the absence or starving of which no adequate excuse can be formulated by a Christian or, indeed, by any other community. We shall not say more to-day. The following meetings are to be held in every part of London in the coming week preparatory to Hospital Sunday:—On Monday, the 13th, at 8.30 P.M., Newington Parish Mission Hall, Kennington-road, S.E.; on Tuesday, at 3 P.M., Mansion-house, E.C.; on Wednesday, at 8 P.M., St. Andrew's Hall, Newman-street, W.; on Thursday, at 4 P.M., Kensington Town Hall; on the same day, at 8 P.M., Wellington Hall, Islington; on Friday, at 4 P.M., Westminster Town Hall; on the same day, at 8 P.M., Stratford Town Hall; on Saturday, at 3 P.M., the People's Palace, Mile-end-road. It is devoutly to be hoped that no sensational politics and no exceptional excitement will interfere to prevent a full appreciation of the wants of these great but quiet institutions, and of the strong arguments which appeal to the favourable consideration of the highest authorities in Church and State, including Lord SALISBURY, who, to his great credit, has engaged to speak at the Mansion House on Tuesday in this cause. We shall, as is our custom, refer at greater length in our next issue to the unparalleled claims our hospitals have on "sweet charity."

Annotations.

"Ne quid nimis."

THE CONTAGIUM OF SCARLET FEVER: JAMIESON AND EDINGTON'S RESEARCHES.

THE remarkable chain of evidence whereby Dr. Klein has been enabled to substantiate the results of Mr. Power's investigation upon the transmission of scarlet fever direct to man from the cow seems to leave little room for scepticism that in the streptococcus met with by Dr. Klein we have the effective agent in the etiology of this disease; and, scanty as prior observations are, imperfect as many of them have been, it is noteworthy that hitherto the scarlatinal microbe has been described as a micrococcus. Coze and Feltz found micrococci in scarlatinal blood; Cornil in the urine in scarlatinal nephritis; Babes describes streptococci in post-scarlatinal inflammatory products; and Pohl-Pincus found "very minute micrococci adhering to the scales of

Digitized by Google

the desquamating epidermis in scarlatina" (von Klein: "Micro-organisms," third edition). The isolation, cultivation, and successful inoculations practised by Klein, however, far outweigh all such partial observations. But, as in the case of diphtheria, so here, it would seem that other observers have arrived at the conclusion that the scarlatinal microbe is a bacillus, and not a micrococcus. Drs. Jamieson and Edington of Edinburgh University have completed a series of observations, which arrive at this result: their plan of procedure being to examine the blood of scarlet fever patients as early as possible, to sterilise an area of skin and protect it from contamination till desquamation occurs, and then to examine the desquamated epithelia for organisms. They found a bacillus in each of these media, and succeeded in reproducing a disease like scarlet fever in calves and other animals inoculated with pure cultivations of this bacillus. Further tests by examination of the blood of the inoculated animals and pure cultivations therefrom also yielded positive results. Until the details of their research are published it would not be fitting to attempt any critical comparison between them and those obtained by Dr. Klein. The fact that the blood of scarlatinal patients has been frequently examined without result makes it at first sight more probable that the minuter organism has been overlooked; but much also depends upon the technical skill of the observer, and bacteriological methods are daily being perfected. It is curious that a disease so obviously contagious as scarlet fever should hitherto have baffled the attempts made to isolate its virus, and that almost simultaneously investigations should be in progress with this object, and with such apparently conflicting results.

DEATHS IN THE MIDST OF FIRES.

THE usual outburst of emotional carefulness has been called forth by the catastrophe at the Opéra Comique in Paris. The deplorable destruction of that place of entertainment, with the serious loss of life it involved, must be regarded as a *catastrophe*, for the preceding history of the construction and general arrangements of the Opéra Comique culminates methodically in what seems to have been pretty generally anticipated and has at last occurred. It is only natural that we as a people, and particularly the people of London, should be agitated to a considerable extent by the calamity. We cannot be ignorant of the dangers that beset our own enjoyment of theatrical performances, and which indeed, as is beginning to be recognised, threaten the visitors to Exeter Hall and the worshippers in crowded churches or chapels scarcely less urgently than playgoers. Already the excitement, which has been less than usual amongst ourselves, is subsiding, and in another week or two the affair will, doubtless, be forgotten, except by those who have been personally affected by it. Meanwhile, it may be well to point out that, although the idea of being "burned to death" in a crowded place of assembly is a very hideous one, in all probability the experience is, like most other modes of exit from this wonderful life of ours, less agonising than it appears. Practically, the burning seldom occurs in these cases until after death, or, at least, insensibility to pain, has been produced. Except under very peculiar conditions the victim is asphyxiated—that is, rendered faint and pulseless—by the carbonic acid gas or by the carbonic oxide, before the fire reaches his body. Anyone who has been in a burning house will know that the heated and smoky atmosphere speedily induces a feeling of powerlessness and at the same time of indifference to what is going on around. It is generally this stupefying of the cerebrum, with subsequent paralysis of the nerve centres, that prevents judicious means being taken for escape; and unless the sufferer has the presence of mind to stoop almost to the ground so as to keep his head below the level of the smoke, he is almost sure to sink without much feeling in the midst of the fire instead of pushing forward. It is well to know and bear in mind this fact, both for the sake of precaution, and to mitigate some of the acute grief which must be experienced at the loss of friends by fires such as that which has just occurred in Paris. We do not, of course, deny that there may in some exceptional instances be a certain amount of suffering in the case of persons so dying, but we doubt whether the proportionate amount of pain in deaths amidst fires is actually greater than that endured by those who die from ordinary disease. There is the element of time to be considered. In place of days, or perhaps weeks, of pain, the whole experience is over in a few minutes at most, without either expectant misery or prolonged consciousness of the approaching end, and, so far as science can determine, it is by no means probable that the intensity of the agony is greater than that of an ordinary death; possibly, even, owing to the rapid generation of the gases, it may be less. This is a view of the case on which it is more pleasant to dwell than that which thrusts itself immediately on the attention when such appalling events as those to which we refer are brought under notice. If the facts were present to the minds of those who now madly rush out of a burning house, to the very great diminution of their chances of escape, perhaps they would induce a little more composure, and thus help to render the loss of life less extensive.

THE METROPOLITAN ASSOCIATION'S IMPROVED DWELLINGS.

THE Metropolitan Association for Improving the Dwellings of the Industrious Classes has just issued its forty-third annual report, for presentation to the shareholders at the approaching annual meeting. This Association has the distinction of having led the way in the invaluable movement for improving the dwellings of the working classes, which is slowly but surely effecting incalculable benefit on the housing and sanitary and social condition of the London poor. Compared with the operations of the Peabody Trust, and one or two of the larger companies carrying on this work, those of the Metropolitan Association are moderate in extent, but the report tells us that the buildings of the Association, situated in fourteen localities, had, during the year ending with March last, an average population of 6115 persons. This was rather less than a third of the population of the Peabody buildings at the end of last year. It is stated that 97 deaths were recorded in these buildings during the year, equal to 15·9 per 1000 of the population, which the report points out is 4 per 1000 below the general rate for the whole metropolis. It must, however, be remembered that no correction is made for deaths recorded in the workhouses, hospitals, and lunatic asylums of the metropolis, a proportion of which should be debited to this population. The deaths in public institutions in London during last year were equal to 4·1 per 1000 of the population. If we debit the Metropolitan Association Dwellings with their full share of these deaths (probably in excess of the true proportion), the corrected death-rate would but slightly exceed the general rate in London, and the rate in the Peabody Buildings last year. This corrected rate would, moreover, still be a most satisfactorily low rate for a working-class population such as that which inhabits both the Peabody and Metropolitan Association Improved Dwellings. The Metropolitan Association report also states that the rate of infant mortality in those dwellings was equal to 164 per 1000 of the registered births, against 159 in the whole of London and 149 in the Peabody Buildings. It is worthy of note, however, that the birth-rate in the Metropolitan Association Dwellings is stated to have been only 32·9, whereas in the Peabody Buildings it was 42·4.

Digitized by Google

Unless the age distribution of the Metropolitan Association population differs very remarkably from that of the Peabody population, it appears probable that the birth-rate in the former is understated, the effect of which would be to overstate the rate of infant mortality. After full allowance for all possible defects in the vital statistics of the Metropolitan Association's report, there can be no doubt of the beneficial effects of these improved dwellings upon the health of their population, or of the important reduction in the death-rate of many parts of London that would result from the further extension of the operations of this and of other companies for the improvement of the dwellings of the working classes.

THE BOARDING OUT OF PAUPER CHILDREN.

THE case of the St. Pancras children boarded out at Denmead does not greatly alter the public opinion as to the merits of the boarding-out system. In some respects it confirms the belief that the system is preferable to that of huge pauper schools. The report of Mr. Clarke, the medical officer of the Leavesden Schools, who was sent by the guardians to examine the children and inspect the homes in which they lived, leaves on the whole a favourable impression. The children were better than when they went to the country, and they were happier—at least they had no wish to leave. They one and all said most distinctly they would not like to return. So strong a human liking for them had taken possession of some of the foster-parents that they refused to give the children up, even if the guardians should withdraw the 4*s.* a week for their support. Some of the houses were clean and comfortable and all that could be desired. There was, it is true, another side to the picture. Some of the foster-parents were old and infirm or in ill-health; one in particular was dirty; another kept a sort of old-clothes shop. The sleeping accommodation in several homes was insufficient; while in seven of the ten homes there were more than two children boarded out—and, it appeared, somewhat promiscuously,—and some of the children looked dirty and neglected. On the top of these drawbacks Mr. Clarke adds: "notwithstanding all this, the children had improved since they came to Denmead." The fact appears to be that there has been a want of care in the selection of fit houses and foster-parents, and that the local committee of supervision has been a little too formal in its duties and trusted too implicitly to the foster-parents. One other point strikes us: that the sum allowed is not such as can compensate the foster-parents for adequate treatment of the children.

MEDICAL OBJECTIONS TO VACCINATION.

UNDER this heading a contemporary publishes a letter signed by persons holding medical qualifications, in which it is argued that there is no ground for claiming that the reduction in the death-rate from small-pox is due to vaccination, because leprosy has also disappeared from this country without any special means having been resorted to for its prevention. The writers omit to mention that the evidence with regard to vaccination is based upon the behaviour of small-pox among vaccinated and unvaccinated persons respectively, that the latter suffer from small-pox as severely and as fatally as heretofore when they are attacked, and that it is only the unvaccinated who enjoy the benefits of more recent times. What are we to think of persons with medical qualifications who make a statement such as that to which we refer to a public consisting of many who have no means of judging for themselves, and who are likely enough to be misled by such teaching? For the ignorant we can feel regret; but a terrible responsibility devolves upon all who by mistaken advice may—unintentionally of course—be the means of introducing disease and death in many a family.

GYMNASTICS AT SCHOOL.

THE honorary secretary of the National Physical Recreation Society gave some interesting evidence lately before the Royal Commission on Elementary Education, and it had the advantage over much of the other matter collected by that body of being statistical in large measure. Speaking of the work done by the Liverpool Gymnasium for the treatment of spinal curvature, he stated that some 3000 cases had come under his own observation there, of which 2500 were cases of children between the ages of eight and fourteen years, 2000 of these being girls. There can be no doubt, we think, that deficient physical exercise, if not the only or even perhaps chief cause of this very common deformity, is highly calculated to promote it; and, even apart from any specific evil, a well-considered and systematised plan of training for the muscles is undoubtedly a most valuable regimen, and eminently adapted to preserve and benefit the general health. But it is of the highest importance, in following out this object, to avoid pernicious exercises, which may do irreparable mischief to the growing organs and unbraced body of a child. The following instance is very much in point: "The care-taker commanded them all (like children of an elementary school) to keep their knees stiff and touch their toes with their hands, and while he kept them in that position he proceeded to give them an impromptu discourse upon the benefit of physical training. When the children rose up you could tell from the hectic colour of their cheeks that they were evidently suffering at that moment from palpitation of the heart caused by leaning down in this extraordinary position." Equally sound appears to us the following comparison between the horizontal and the parallel bars: "In the case of the horizontal bar, or anything pendent, children naturally jump up and get on with their hands together; that is a position of contraction; the chest is contracted and the shoulders brought forward, unless they have a very painstaking instructor, who will make them widen out their hands and change frequently. In the case of the parallel bars, the ordinary position of a child upon it causes expansion of the chest; the very movement of resting upon the parallel bars is one of expansion, without any teaching whatever."

"ACROMEGALY."

ANOTHER example of the curious and rare condition of acromegaly of which an account was first given by Dr. Marie (THE LANCET, 1886, vol. i., p. 1060) last year, has been recorded by Dr. Minkowski (*Berl. Klin. Woch.*, 1887, No. 21). The case occurred in the medical clinic at Konigsberg, the subject being a musician, thirty-eight years old, who for some years past had experienced a gradually increasing size of the hands and feet, so that he could no longer play the violin. The nose and ears also became thickened, and the whole form of the face altered. He had suffered much from headache, and his vision had become gradually impaired; he had also become somewhat deaf. He was a man of medium height. The hands were strikingly enlarged in width and thickness, the fingers especially, the thickening involving both bones and soft parts. There was no œdema. The forearm was disproportionately enlarged. A parallel increase in the size of the peripheral parts was seen in the lower limbs, where the leg and foot were greatly enlarged, as well as the individual toes, the great toe being "gigantic." The patella was notably enlarged. As to the face, the nose, lips, and chin were manifestly hypertrophied, the septum as well as the tip of the nose being much thickened. The lower jaw was thickened and projecting, the zygoma and the orbital margins prominent. The head had a long oval shape. The ears were large, and their cartilages thick. The eyes were prominent, the tongue was large, and the buccal mucous

Digitized by Google

membrane hypertrophied. The laryngeal cartilages were voluminous, the thyroid body apparently atrophied. The muscles were ill-developed. Intellect was normal, but hearing impaired, speech slow, and visual field contracted. Marie's case also had symptoms of polyuria and polydipsia, but otherwise resembled the present one. Dr. Minkowski refers to the opinion of Klebs, who had recorded one of the cases collected by Marie, that the condition was due to a morbid proclivity to excessive vascular development, affecting chiefly the peripheral parts. It is noted that in the cases as yet examined after death the pituitary body has been found much enlarged; in one case (Henrot's) it was of the size of a hen's egg; in another (Brigidi's) it had caused enlargement of the sella turcica and compression of the optic nerves. The thyroid has been found in some cases atrophied, in others greatly hypertrophied. One case has been recorded as myxœdema, but the resemblance between the two conditions is only superficial, the osseous changes and the absence of cutaneous lesion in acromegaly, together with the wholly different physiognomy, sufficiently marking the difference. In Virchow's leontiasis ossea there is no such disproportionate enlargement of the extremities, and in Paget's osteitis deformans the long bones and cranial bones are chiefly affected, whereas in acromegaly the facial and not the cranial bones are involved, and the distribution of the changes in the limbs is invariably symmetrical.

THE NATIONAL HEALTH SOCIETY.

THE fourteenth annual report of the National Health Society is published. The work of the Society consists chiefly in providing for the delivery of lectures on subjects more or less connected with personal and national health. Among the lecturers were Mr. Shirley Murphy, Mr. Malcolm Morris, Mr. Frederick Treves, Dr. Greenwood, and Dr. Barnard O'Connor. The last-named gentleman, at the request of Canon Cromwell, gave a course of lectures on the Laws of Health, at St. Mark's Training College, Chelsea, for the instruction of young men training for schoolmasters. The Society, whose office is at 44, Berners-street, is glad to receive applications for short courses of lectures for district visitors, mission women, cottage mothers, &c. We think such a society likely to do a great deal good, if it keeps to sound lines and does not attempt too much.

THE CHILDREN'S FÊTE.

THE 21st of June will be marked by many noteworthy signs of rejoicing in different parts of the country. Perhaps none of them will afford Her Majesty a more appropriate tribute of congratulation on the completion of the fiftieth year of her reign than the colossal assemblage of London school children in Hyde-park. Of all the changes that have come to pass during that long and prosperous period, none is more significant of the growth of our national life or more full of hope than the formation of our system of State education. We therefore wish all success to the intended demonstration. If, at the same time, we point out some of the difficulties which belong to so great an undertaking, it is only because we desire to ensure its success, and to prevent the chance of regrettable consequences. The plan of transit may be safely left in the hands of those who will organise the practical details of the scheme. What chiefly concerns us is the condition and surroundings of the children. It is to be hoped that in making the selection of those who will attend the gathering due regard will be paid to the subject of health. Not prominence in classwork alone but fitness for the journey should be taken into consideration. Weather is an uncertainty which must also be reckoned with. These, perhaps, may seem to be mere commonplaces, though they are important trifles. Scarcely so obvious, but even more pressing, is the necessity that no child should atttend in the park about whom there lingers a trace of infectious disease. This year has seen an unusual prevalence of measles and whooping-cough among the urban poor. Is it necessary for us to add the caution that the person and home of each of this multitude of children should be certified as free from any taint of infection? It may prove calamitous for many of the children if this matter does not receive the strictest attention.

MEDICAL ASPECTS OF THE MISSION TO DEEP-SEA FISHERMEN.

THE annual meeting of the Mission to Deep-sea Fishermen was an interesting one from a medical and humanitarian point of view, Sir Andrew Clark occupying the chair, and addresses being given by him and by Mr. Frederick Treves, F.R.C.S., who had himself personally inspected the work in the North Sea and had seen the great need existing among the 1200 fishermen there for the medical and surgical aid now as far as possible supplied by the mission smacks, which are provided with a medicine chest and various surgical appliances, and which carry a skipper and seamen who have gone through a course of instruction by Dr. Schofield, so that a man who meets with a lacerated wound or a fracture of the arm whilst conveying fish boxes in a little boat from his smack to the steamer running between the fleet and Grimsby can be, if a mission smack is near, promptly and pretty efficiently treated. A great want, however, is still unsupplied, and that is a floating hospital, neither the mission nor the other smacks having berths suitable for sick or injured men. Another great advantage of the mission smacks is that they have to a large extent driven the "copers," with their vile and unwholesome spirits and tobacco, and their still more vile literature, off the seas, they themselves selling good tobacco, warm woollen mittens, "helmets," and other clothing, and pure healthy literature, but no alcoholic liquors. A magnificent gift of a steam yacht has just been received by the Deep Sea Mission. This will be just the thing for the work, and a few sick berths might well be fitted up in her. She might even "carry a surgeon," but unfortunately the society is so pressed for funds that it is quite uncertain whether the yacht can be even manned and put to sea.

ACUTE GRAVES' DISEASE.

AN apparently well-authenticated case of Graves' disease, having a total duration of six weeks, and accompanied by remarkable emaciation, is recorded by Dr. Michell Clarke in the *Bristol Medico-Chirurgical Journal*, No. 15. It was that of a girl, aged eighteen, a native and resident of Chepstow, whose family history was good, and who had always enjoyed perfect health till 1885, when she experienced headaches occasionally, with slight feeling of fulness at the throat; and again in June, 1886, during a menstrual period, violent palpitation, severe frontal headache, pain in the præcordial region, and nausea with vomiting in the morning; but this group of symptoms disappeared, and the next menstrual period was completed without the occurrence of any abnormal symptoms. She remained well until Aug. 4th, when the palpitation returned, and the symptoms of exophthalmic goitre appeared, together with a nasal voice, slight cough, and rapid emaciation. On admission, the notes show great mental excitability and slight choreiform movements of limbs. Von Graefe's symptom was well marked. Towards the end of the case diarrhœa and vomiting were remarkable symptoms. The patient died on Sept. 14th. Dr. Michell Clarke observed that the thymus

Digitized by Google

was very large, as in two instances of exophthalmic goitre recorded by Hilton Fagge; the liver and pancreas were very small; the thyroid very large; the exophthalmos had disappeared; microscopic sections of the central nervous system and the cervical sympathetic revealed nothing abnormal.

OVERLAIN CHILDREN.

WHEN a coroner tells us that he has observed more than 200 cases in which children have been overlain and suffocated by a parent, we are tempted to ask whether this accident has always resulted from mere carelessness. A misfortune so simple in its causation may doubtless easily happen in the overcrowded homes of the poor where a number of children are huddled into one or two small rooms. Nevertheless when one finds it repeats itself so frequently, and even occurs more than once in a single family, the conviction that there has been gross neglect cannot but carry with it some suspicion of design. Infantile insurances, and the poverty of hard times, are pressing inducements which might suffice to justify in the minds of unscrupulous parents the wilful contrivance of such an accident. Coroners and insurance companies alike will therefore do well to inquire with particular closeness into the details of any case of the kind which may come before them, and every motner who would merit the reputation of even ordinary care should take the advice of Dr. Danford Thomas and allow her infant a separate cot.

CATTLE DISEASES IN GREAT BRITAIN.

PROF. G. J. BROWN, in his annual report for the year 1886 of the Agricultural Department, Privy Council Office, states that the last reported outbreak of foot-and-mouth disease occurred in October, and that it may be concluded that the disease has ceased to exist in this country. Respecting pleuro-pneumonia the report is less encouraging, there being slightly fewer outbreaks in England than in 1885, but more cattle were attacked; whilst in Scotland the outbreaks extended in area, and the cattle attacked were more than twice as numerous as those affected in 1885. Many of these outbreaks were traceable to Irish cattle, and the subject of the possible conveyance of the disease from Ireland is being considered, as well as the measures to be taken to deal with it. Mr. Brown discusses the measures for the extinction of pleuro-pneumonia, and declares that nothing short of the stamping-out system is efficacious. Protective inoculation, which had been advocated in Scotland, is objectionable from the probability that infected cattle may be inoculated with great risk to the spread of the disease, and he states that no country has been yet successful in getting rid of pleuro-pneumonia by inoculation. Swine fever appears to have been very prevalent in various parts of the year, the variations being attributable more to the amount of trade carried on with these animals than to the enforcement of restrictive measures. This disease was made the subject of a Parliamentary report last year, one object being to aid in the discrimination of the disease from other diseases of swine; and experimental inquiry into protective inoculation is in progress, but it is pointed out that the ordinary methods of attenuation of virus could not be applicable, since it would be necessary to have the power to inoculate a herd from the infective matter of the first case arising in it. Perhaps the desired result might be attained by diluting the virus through admixture with certain chemical agents. Anthrax, which by order of Council was last year brought under the operation of the Act of 1878, forms the subject of some interesting paragraphs in the report. The wide prevalence abroad, especially in France, as compared with this country, is noted; and the possibility of its introduction through infected wools, skins, fodder, litter, and manure is illustrated by a reference to the occurrence of wool-sorters' disease. It is pointed out that it would be practically impossible to prevent the importation of infected wool. Anthrax is generally limited to the farm on which an outbreak occurs, and, owing to the rapidity with which it kills, nothing would be gained by adopting the stamping-out system with a view to its eradication. The importance of avoiding any effusion of blood of the diseased animals is emphasised, post-mortem examination being unnecessary for diagnosis, which can be at once effected by microscopic examination of a drop of blood. Protective inoculation has not been as yet needed in this country, but it is encouraging to learn that experiments are being made to test the value of certain chemical agents in modifying the activity of the virus or rendering the animal insusceptible to its influence.

THE CHURCH BELL GRIEVANCE.

WE are sorry to be unable to endorse the opinion that the question of church bells "is one for judicious compromise," though we agree that it "should be approached without anything like temper on either side." It is confessedly difficult, to the extent of being impossible, to preserve anything like equanimity when a dear friend has been seriously injured, perhaps hurried into a state of cerebral excitement which has ended in death, by the ringing of bells in churches. We cannot designate the church bell question one of nuisance; it is more than that, for direct injury is done; and, for ourselves, we should certainly advise practitioners who have patients suffering from this annoyance to refuse certificates in the event of death being hastened by this wanton noise-making. We entirely agree with a correspondent of one of the daily newspapers, who thinks that the question must be fought out by strong contention. As a matter of law, we are decidedly of opinion that church officials are, in strictness, only entitled to ring or toll bells previously to "morning" and "evening" prayer and for funerals, and that all extra ringing previously to sacramental and other occasional services, now so numerous, are absolutely without warrant of statute or custom.

MEMORIAL TO THE LATE DR. WILSON FOX.

A DESIRE has been widely expressed that there should be some memorial to the late Dr. Wilson Fox. It has been thought by some of his most intimate friends that the memorial should be personal, and that the most appropriate form would be a portrait, to be presented to Mrs. Wilson Fox. It is proposed, if the amount of the contributions permit, that replicas shall be made for the College of Physicians and for University College. For this object a committee has been formed, consisting of Sir William Jenner, Dr. Russell Reynolds (treasurer), Mr. Erichsen, Mr. George Pollock, and, as secretaries (to whom contributions can be sent), Dr. Gowers, 50, Queen Anne-street; and Dr. Barlow, 10, Wimpole-street.

PLACENTA PRÆVIA.

BAYER, in the *Centralblatt für Gynekologie* (No. 25), discusses the relations of the lower segment of the uterus to placenta prævia as held by different observers. He thinks that the condition of the uterus in this affection is often similar to that in premature labour—i.e., that in both the supra-vaginal portion does not undergo the usual changes, and that the internal os remains closed till labour. According to this view, no hæmorrhage occurs during pregnancy except when a part of the placenta actually covers the internal os, and even then only when the internal os dilates during pregnancy, which it does not always do

Digitized by Google

Bayer recommends the following classification of cases of placenta prævia: 1. Cases in which the placenta covers the os, and in which the expansion of the supra-vaginal portion occurs at the usual time. In these there will be hæmorrhage during pregnancy, and secondary changes will be found in the placenta. 2. Cases of placenta prævia in which the cervix continues intact right on to labour. No uterine hæmorrhage occurs during pregnancy, and consequently no secondary changes will be found in the placenta.

HEALTH OF CALCUTTA.

THE death-rate in Calcutta for the first quarter of the year was 27·11 per 1000, being about 1·5 per 1000 above that of the same period in the preceding year, but lower than in any other year of the decade. The principal causes of mortality were fevers, by which the deaths were 7·51 per 1000 of the population, dysentery and diarrhœa 3·55, and cholera 3·47. The deaths from cholera were only 77 in January and 82 in February; but in the first week of March they experienced a sudden increase, and the total for that month amounted to 216. The latter number corresponds very closely with the average for the month of March during the last decade. Dr. Simpson, in his report, gives the details of an investigation into the probable cause of two special outbreaks of cholera, one on board the ship *Ardenclutha* in the river, and the other in Howrah. They were pretty clearly traced to the milk supply, which had been contaminated by being diluted with water from a tank which had been fouled with the excreta of a cholera patient. In a special memorandum on the reorganisation of the health department of the municipality, Dr. Simpson has brought under the consideration of the authorities two very important subjects—the appointment of qualified inspectors charged with the duty of making periodically a house-to-house visitation to ascertain the real sanitary condition of the dwellings, and the imperative need of an increase to the numbers and reorganisation of the duties of the staff of the health officer. We sincerely trust that these subjects will meet with the consideration they deserve from the sanitary commission.

SMALL-POX HOSPITAL EXPENDITURE.

THE Islington guardians have expressed sympathy with their representative who, at a recent meeting of the Metropolitan Asylums Board, showed that every small-pox patient had during the last six months cost £34 per head per day, and urged the closing of the hospital ships. It is impossible to tell how long London will remain free from small-pox, but to close the ships would be to expose London to a definite risk; it does not need the aggregation of more than a few cases of small-pox in hospitals situated in a populous neighbourhood to give rise to an outbreak, and though this would undoubtedly have the effect of reducing the cost per head, the total expense would necessarily be greater. We doubt if this result would be satisfactory to the Islington Board of Guardians or to any other of the London local authorities. The Metropolitan Asylums Board, acting in the interest of the ratepayers, regard themselves as a sanitary authority, and hold that they are doing a more useful work in preventing disease than in merely providing hospital accommodation for those who suffer from it. Dr. Edward Seaton has recently urged that the Metropolitan Asylums Board are justified in advocating the means for preventing the infection of persons for whom it would be their duty to provide accommodation if they were attacked with such illness. No doubt the interests of the ratepayers, both as regards the saving of life and the expenditure of money, will be best ensured when these two functions are in the hands of one administration. One of the greatest of London's wants is a central sanitary authority.

THE MEAT SUPPLY OF GIBRALTAR.

THE authorities at Gibraltar propose to abolish the importation of meat from Tangier. This decision has already occasioned loud protests. It is urged that a great number of persons derive their means of existence solely from slaughtering cattle and preparing meat for the garrison and population of Gibraltar; that it is easier and cheaper to take meat than live cattle across the Strait. In considering this matter, it must be born in mind that the all-important fortress of Gibraltar derives the greater part of its fresh meat supply from Africa—that is to say, from Tangier. The distance across the Strait is thirty-eight miles, and the sea is often very rough. Nor is there any port at Tangier; the steamers must anchor in the open bay, and the cattle are brought to them in flat-bottomed barges and then swung on board after much labour and trouble. In the face of these circumstances, it is much more simple to kill the bullocks at Tangier and send the meat over. Thus the trade in meat has been developed; and not only does it supply work for a great number of persons at Tangier, but the sums paid for the use of the slaughterhouse go in part to defray the cost of various charitable institutions. Finally, the town imposed a shilling tax on every head of cattle killed, and this pays the wages earned by the scavengers who, at rare intervals, are sent out to clear the streets. In spite, however, of all these arguments, it is impossible not to approve the action of the authorities at Gibraltar. The slaughterhouses at Tangier, both the Jewish and the Moorish, are indescribably filthy. In England such establishments would at once be closed by the police. They are a standing nuisance and gravely endanger the public health. No attempt is made to drain the slaughterhouses. The blood runs away in an open ditch down to the beach, and falls into the sea close to a spot generally selected for bathing. The ditch is so foul with blood that horses and mules are sometimes afraid to step over it. Perhaps, now that the inhabitants of Tangier find they are about to lose a lucrative source of income, the necessity of building a proper slaughterhouse and imposing regulations in keeping with the laws of hygiene will at last be admitted. In any case, and in self-defence, the authorities at Gibraltar have done well to bring such wholesome pressure to bear. Gibraltar is intensely overcrowded. At Tangier there is any amount of vacant space, and the climate is better and the air purer. It would therefore be preferable that the cattle should be slaughtered at Tangier; but only if this can be done under proper sanitary control, in slaughterhouses with cemented and well-drained flooring, where the most perfect ventilation and cleanliness are maintained.

SHEFFIELD MEDICAL SCHOOL.

IT will be remembered that the need for fresh premises for the Medical School at Sheffield was brought prominently before the public last October, when a meeting was held at Firth College, at which the Archbishop of York and Sir Andrew Clark were present. The amount required was £6000, and the appeal for assistance has been so well received that the Council now feel justified in proceeding with the erection of the new premises. A site containing about 550 yards, situated in Leopold-street, opposite Firth College, has been secured, and Dr. Bartolomé, president of the school, is expected to lay the foundation-stone about the 16th or 17th inst. The plans which have been prepared give the school a handsome outward appearance, and provide all the accommodation needed. The main elevation is entirely of stone, and the treatment a sort of free Classic Renaissance, which will cause the building to harmonise well with the surrounding property. The contractors expect to have the premises completed by next March.

THE IRISH EXAMINING BODIES.

THE College of Surgeons of Ireland have not abandoned ll hope that the Irish medical corporations may still comine to form one examining body. At a meeting held on aturday last the Fellows of the College adopted a motion f Sir Charles Cameron to the effect that a fresh attempt hould be made to procure the much-needed combination, he General Medical Council having recognised the Apothearies' Hall as a medical corporation; and, further, they xpressed the opinion that, should an attempt again fail, he College considers that the Council (we presume that of he College) should, if possible, form a combination with the pothecaries' Hall. The proposal was seconded by Dr. Kidd, nd carried. We sincerely trust that the Apothecaries' Hall vill agree to this course. There is not, we fear, much hope hat the College of Physicians of Ireland will at this stage eize this excellent opportunity of proving that their interest n the welfare of the profession is so great as to make them lepart from their previous decision, but the Apothecaries' Iall have before now shown their willingness to combine.

HERPES IN PHTHISIS.

AN interesting paper in the *Gazette Médicale des Hôpitaux*, No. 9, 1887, by E. Barié, brings together much information on a rare condition met with in tubercular subjects, and formulates the following conclusions. Zona is a rare complication of chronic pulmonary phthisis, usually affects the thoracic walls, but may occur in the neck, face, loins, upper and lower extremities, and even the perineo-genital region. The eruption, sometimes accompanied by motor and thermal disorders, has been set down to vaso-motor perturbations possibly of reflex origin, but this explanation is insufficient, and the zona of tubercular subjects may be connected with a tuberculous meningo-myelitis, or more often with a parenchymatous peripheral neuritis.

THE IPSWICH INQUEST.

THE unfortunate death of Bertha Wall, aged sixteen, a pupil at the Ipswich High School, has been the cause of serious differences between the coroner on the one hand, and the jury and representatives of the press on the other. It may be remembered that the body of the deceased was found in a pond near Akenham. The evidence went to show that death resulted from drowning; the jury ultimately returned an open verdict. From information received, the coroner, Mr. Vulliamy, in the exercise of his discretion, decided to proceed with the inquiry with closed doors. The jury and certain members of the press took umbrage at this, and resented it, to the extent that the former refused to serve unless the reporters were admitted, and the latter on their part insisted on being present. After several adjournments the case was investigated in private, the Lord Chancellor having adjudged the coroner within his legal rights in excluding the press. This decision is founded on statute, which empowers the coroner to conduct his inquiries in public or private as he may deem fit. Whilst regretting the exclusion of reporters, we are bound to admit that if the responsible judicial authority is of opinion that matters will transpire the nature of which will be likely to shock and injure decency and morals, he is acting wisely in refusing admission to the general public. In the present instance no one seems to have disputed the point that some extraordinary revelations would be made at the inquest—revelations the result of which it would be difficult to foresee as regards their individual and collective application. We fully acquiesce in the contention that guilt should be visited with its just reward, even to the extent of public exposure, providing public morals are not abused thereby. There is a duty to the living as well as the dead, and no demand can be more urgent than that which calls for the protection of the mind of youth from the exposure of revolting details. Prior to the completion of the inquiry the coroner committed a member of the press for contempt of court, in that he openly advised the jury not to be intimidated by the coroner. The same evening a writ of *habeas corpus* was obtained from Mr. Justice Grantham in the terms asked for—viz., that the prisoner should be admitted to bail pending an application to quash the warrant of commitment. The incident was terminated by the coroner ordering the release of the prisoner, the latter having apologised for any remark he might have made constituting contempt of court.

UNIVERSITY COLLEGE, LONDON.

DR. WILLIAM RAMSAY, Principal of, and Professor of Chemistry in, University College, Bristol, has been appointed to fill the chair of chemistry in University College, London, vacant by the resignation of Dr. Williamson. Dr. Sydney Ringer, F.R.S., has been appointed Holme Professor of Clinical Medicine, in succession to the late Dr. Wilson Fox. Mr. Victor Horsley, F.R.S., has been appointed Professor of Pathology, in succession to Dr. Bastian, resigned. The first award of the Slade Travelling Scholarship (value £150 per annum for two years) has resulted in the election of Mr. Harrington Mann of Glasgow.

PROFESSOR BILLROTH.

A RUSSIAN daily paper of the 11th (i.e., the 23rd) of May announced the death of Professor Billroth, whose work, it remarked, had been the text-book of the majority of Russian students. Happily, so far is this statement from being correct, that the condition of the eminent surgeon has greatly improved, and he is now considered completely out of danger. Dr. Hacker, who is doing his duty for the present, announced to the class last week that it was hoped that their great master would himself be able to resume charge of the clinic after a rest of six months.

THE APPROACHING COLLEGE ELECTION.

WE understand that Messrs. Willett, Brudenell Carter, George Cowell, and James Rouse are likely to be candidates for election to the Council of the Royal College of Surgeons. The retiring members are, Sir T. Spencer Wells and Messrs. Jonathan Hutchinson and John Wood, of whom the two former at least will probably seek re-election. Nomination papers must be sent in before July 13th.

CEPHALIC VERSION IN PLACENTA PRÆVIA.

DR. KUFFERATH, Professor of Midwifery at the University of Brussels, in a clinical lecture on cephalic version, expresses an opinion that it is bad practice to resort to this operation in cases of placenta prævia; we cannot hope, he says, to arrest hæmorrhage by changing a malpresentation, for the head, in cases where cephalic version is still possible, will not plug the bleeding surface.

DEATHS OF EMINENT FOREIGN MEDICAL AND SCIENTIFIC MEN.

THE deaths of the following foreign medical and scientific men are announced:—M. Henri Issartier, Senator of la Gironde and Mayor of Monségur. M. Issartier had long given up the practice of medicine, and had devoted himself to horticulture and scientific agriculture. He published a treatise on the Cultivation of Fruit-trees and a Course of Agriculture.—Dr. A. U. Giubner, a well-known Russian military surgeon.

THE ILLNESS OF THE CROWN PRINCE.

DR. MORELL MACKENZIE has again visited the Crown Prince, and on Wednesday last he removed another portion of the growth on the vocal cord by laryngeal forceps. The Crown Prince will travel to London next week, and after the Jubilee festivities it is expected that a long stay will be made in the Isle of Wight, so that Dr. Morell Mackenzie may conclude the treatment of his Imperial patient.

PHARMACEUTICAL CONFERENCE.

AMONGST other subjects upon which the secretaries of the Pharmaceutical Conference, which is to be held next August, invite papers, are the following:—The alkaloidal strengths of narcotic extracts compared with that of the fresh juice; the quality of cacao butter; the application of dialysis to pharmaceutical processes; the strength of tinctures and liquid extracts; the cause of the variations in the value of salicylate of sodium; the active principles of ergot, senna, colocynth, jalap, aspidium, felix mas, lactucarium, senega, taraxicum, and buckthorn.

MEDICAL LEGISLATION IN BELGIUM.

THE Belgian Legislature has just had before it a new Bill concerning university examinations and academic regulations. The proposals to re-establish the arts degree as obligatory for medical students and a final State examination for a licence to practise did not meet with much favour. Some changes were, however, voted in the programme of medical studies; thus, the special course of embryology is to be abolished, and this subject included in the course of general and special histology; also the elements of pharmacy, together with the course on pharmacognosis, are to form part of the programme for the first Doctorate. The necessity of a better acquaintance with legal medicine and toxicology has been recognised, but no fresh examination has been imposed. Some of these changes will doubtless affect the numerous British practitioners who, under existing circumstances, resort to Brussels for the degree which is denied them in London. Another regulation has been made as the result of the representations of Belgian medical men, who have for a long time been complaining bitterly of the competition to which they have had to submit from foreign practitioners, especially at Ostend and other watering-places, for English and German practitioners have hitherto been able without much difficulty to obtain a licence to practise in Belgium upon the strength of their existing diplomas. Now, however, all foreigners will be obliged to pass an examination and obtain the recommendation of the central jury before permission to practise in any part of Belgium can be obtained.

FOREIGN UNIVERSITY INTELLIGENCE.

Berlin.—The number of university teachers of all grades is now 290, of which 104 belong to the Medical Faculty, including three teachers of odontology.

Vienna.—The vacation short courses of practical instruction for medical men, which have been held for many years past during the months of August and September, are about to be stopped. The prospectus of these courses, numbering more than fifty, had already been published when this decision was arrived at.

SCHLESINGER ON LAPARO-SALPINGOTOMY.

DR. SCHLESINGER, chief of Prof. Slavianski's clinic in St. Petersburg, publishes statistics of 274 cases of laparo-salpingotomy for diseased conditions of the Fallopian tubes. Only four of them seem to be by Russian surgeons, two by Prof. Slavianski and two by Dr. Sutugin, all of which were successful. The total deaths were twenty-four, 245 cases being stated to have been completely cured. Dr. Schlesinger concludes that in pyosalpinx, hydrosalpinx, or hæmato-salpinx laparotomy is the only possible resource, and that generally speaking, though it is by no means necessary to look upon this operation as a *dernier ressort*, it should be performed as rarely as possible.

NEW TEST FOR MILK.

A NEW test for water—that is pump water—in milk has recently been proposed by Herr Szilasi. This depends on the fact that sulphate of diphenylamine is coloured blue by the action of an exceedingly dilute solution of a nitrate. As well water always contains more or less nitrate, its presence in milk can be detected. The test is carried out thus: Twenty minims of sulphate of diphenylamine is placed in a small porcelain vessel and a few drops of the milk which is to be examined added to it. If this contains even 5 per cent. of average well water, a blue tinge will gradually distinctly appear. Sulphate of diphenylamine is easily procurable, and only costs about sixpence an ounce, so the test may be readily tried.

THE Jubilee number of the *Illustrated London News* is accompanied by a coloured plate of Her Majesty, in State Robes, standing near her throne. The work is of the highest finish, and the delicate flesh tints are copied with the greatest accuracy. The number itself contains a pictorial history of Her Majesty's reign, and can be warmly recommended to all who desire to become possessed of such a souvenir of the event we shall all celebrate on the 21st inst.

IN *Scribner's Magazine* for July, Professor D. A. Sargent, M.D., of Harvard College, will publish, as the fruit of many years' practical experience, an article on "The Physical Proportions of the Typical Man." In it the author will give a standard of physical measurement based on the measurements of 10,000 individuals.

A REUTER'S telegram from New York announces that yellow fever has broken out at Key West, Florida. The Government has ordered the mails between Key West and Cuba to be fumigated, and a strict quarantine is enforced at the northern ports.

THE Jubilee offering of a Royal Standard made by the young ladies of Reigate to the Royal Medical Benevolent College at Epsom has been most gratefully acknowledged by the authorities.

AT the last meeting of the Epidemiological Society Dr. Thorne Thorne was elected President for the next session. Mr. R. D. R. Sweeting succeeding him in the office of treasurer.

THE formal opening of the Exhibition of Articles of Food and Drink will take place at Amsterdam on the 15th inst. The Exhibition will remain open till the end of September.

WE are glad to be able to state that Mr. Lund is improving in health, and progressing rapidly towards recovery.

TYNEMOUTH INFIRMARY.—At a recent meeting of the Building Committee of this institution, it having been intimated that the Dowager Duchess of Northumberland would be unable to perform the ceremony of laying the foundation stone, it was agreed that the stone should be laid by Mr. R. M. Tate, president of the committee. The ceremony will take place on the 21st inst.

THE MANX CLIMATE.

By ALFRED HAVILAND,

HOR OF "CLIMATE, WEATHER, AND DISEASE," "THE GEOGRAPHICAL DISTRIBUTION OF HEART DISEASE, CANCER, AND PHTHISIS IN ENGLAND," ETC.

[ANY there are who will for a long time remember the , frosts, and snowstorms of the winter, which we all e has at length left us, although the snows of April and fogs of May have combined to keep it fresh in the nories of the Londoner and of many an invalid in what been called the sunny south. There is an erroneous ression deeply engraven in the public mind that the ;her one goes north the winters become colder and summers less genial. As a general proposition there be no doubt that this is true; but the climates of the ·ld are made up of factors, which, whilst obeying the nutable laws of nature without exception, are neverthe- so interdependent the one on the other as in no two ;es on the face of the earth to be found in exactly the ıe combination, and therefore identical in results. Our at oceanic currents are grand secondary factors in both general and local climates of the earth, and all of se we know to be influenced by the present con- ıration of the great continental areas, their initial ·ction having been originally determined either by that powerful and constant air currents (prevailing winds), by differences in the temperature between equatorial and ar waters, or by both causes combined. Let the reader sult the admirable map of oceanic currents in the hysical Geography" of the late lamented Keith Johnston ıose young life was so recently sacrificed to his devotion geographical exploration), and he will see the course of south equatorial current from the S.E. to the N.W. ected by the north-east coast of South America until it ches the Gulf of Mexico, where the land turns it back, so t after its emergence from this inland sea it is diverted rply to the N.E. by the south-east coast of North erica, and, continuing in the same direction, sweeps by British Isles and the north-west coast of Norway far ond the Arctic Circle, carrying with it the genial warmth h which the south-westerly or anti-trade winds load mselves in their passage over it, and then disseminate ughout Western Europe; Cornwall, Ireland, the Isle of n, and the western isles and coast of Scotland enjoying he fullest extent, from greater proximity to their source, se warm air currents in all their nascent purity; the ılt being, as described by Sir A. C. Ramsay in his ıysical Geology and Geography of Great Britain," t, where these genial influences are first felt, certain den plants grow through the winter, and even in the far th-west of Scotland, which the winter cold of Middle- kills. "I have seen," he says, "fuchsias growing all the r round on the shores of Loch Erribol in Sutherland."

low, the Isle of Man enjoys all the genial influences ribed to climates begotten of the Gulf Stream to the est extent; it therefore will no longer be a matter of ıder that when the befogged and befrosted southerner ded on her shores last winter, or even during this spring, began to think that the learned Dr. John Macculloch, in ting to Sir Walter Scott, was somewhat hasty in his demnation of the opinion of "the author more pro- nd than all his predecessors," who firmly believed that na was the Elysian plain of Homer, "where ocean ·ays sends forth the gentle blowing breezes of the west ıd," for had he not just emerged from the Cimmerian kness of fog-capped London, or just been dug out of a w drift? With a mind filled with such late experiences, impressed with the notion that the winters increase in erity as one goes northward, we ought not to be surprised ıis giving in his adhesion to the Elysian theory when he nd, on landing, no trace of winter, no snow, no fog, and y the history of a brief frost, and when the self-registering rmometers and the sunshine recorders told him of the ·t and light enjoyed in Mona at a time when he was ding his morning letters in London by gas-light, or ng driven in tandem cabs, at extraordinary fares, over ılanches through its streets. This is no exaggeration, , on the contrary, a tame picture of what was ex- ienced by hundreds of visitors last winter and this spring, many a winter and spring before.

The Isle of Man suffers from the ignorance of the public on two subjects—climatology and geography. The former is not taught in medical or any other schools in England, and the average Londoner and Southron gets sorely puzzled when asked to define the geographical position of Manx- land; he generally has no notion whatever about Mona, and if he has somewhere or somehow heard of her, she is generally inextricably mixed up in his mind with the Isle of Wight or Iceland, or in the poetico-geographical mind with Ultima Thule; although some learned Londoners will tell you that the peculiarities of its fauna—to wit, the taillessness of its cats and poultry—"differentiate" Mona from Vectis; this is a grand peg on which many memories are hung. This ignorance is strange when we consider how much interest this lovely island of grand mountain, sea-cliff, and glen scenery has created in times gone by; but perhaps people were then more learned and less "crammed" than they are nowadays in this age of competitive examinations.

The learned Dr. J. F. Berger, who visited this island in 1811, when he examined its geology, took the temperature of its springs, and measured its mountains, in company with Mr. Thomas Scott, the brother of the "author of Waverley," tells us that it was in the Isle of Man that the first attempt was made to use the barometer to determine the altitude of a mountain in Great Britain, and that this experiment was first made by the good Bishop Wilson on Snaefell, by which he approximately ascertained its height; the original experiment, pointed out by Pascal, having been first performed by Périer (his brother-in-law) on the Puy de Dôme, September 19th, 1648. Bishop Wilson came over to the Isle of Man in 1698, where during his long residence he made the experiments that led him to the elevation of Snaefell, which, according to the latest survey, equals 2034 feet. It is also interesting to note that during his stay in the island Dr. Berger took "the temperature of several springs (thirty-one) in all parts of the Isle of Man, to deduce by approximation the mean temperature of the climate of that island," and that he concluded from these experiments "that the mean annual heat in the Isle of Man" was 49·99°. Mr. Alexander Buchan, M.A., F.R.S.E., and secretary to the Scottish Meteorological Society, from observations ranging over a period of twenty-three years (1857-1880), makes it 49·00. For Dr. Berger's interesting observations I must refer the reader to the Transactions of the Geological Society of London. Following the Bishop's example, Dr. Berger measured the altitudes of seventy-seven mountains and other heights, twenty of which ranged from a thousand to nearly two thousand feet above the sea level. These heights he determined by the barometer, and in his calculations made use of Professor Leslie's sliding scale.

From the past I will now proceed to the present. During the exceptionally cold winter quarter of 1886 there actually occurred in the Isle of Man, to the astonishment of most Manx men, a snowstorm which will be long remembered as a most unusual occurrence, like the only too historical snowstorms that have occurred at Melbourne since 1849—namely, those of August 29th, 1849, and July 26th, 1882. As the Isle of Man suffered from the effects of the exceptional winter of 1886, it will be well to see how it came out of the ordeal by comparing the Manx and the south coast winter quarters of that period, Douglas representing the Isle of Man, and Truro, Plymouth, Torquay, Ventnor, Eastbourne, Osborne, Southbourne, and Brighton representing the south coast of England. The mean monthly temperatures were as follows:—

	Jan.	Feb.	Mar.	Mean.
Douglas, Isle of Man	38·9°	38·8°	39·2°	38·98°
South Coast (eight stations)	38·5°	36·4°	39·9°	38·26°
Temperature at Douglas.....	*0·4°	*2·4°	†0·7°	*0·72°

* Excess. † Defect.

These figures speak for themselves, and prove how well Douglas holds its own while the southern health resorts are arrayed against her, even during such an exceptional winter quarter as that of 1886.

I will now give Mr. Thomas Keig's report of his observations made during the three meteorological winter months (December, January, and February, 1886-7) for Douglas:—

	Dec.	Jan.	Feb.	Mean.
Mean Maximum ....●	42·89°	44·48°	42·03°	= 43·13°
Mean Minimum	34·96°	37·34°	42·04°	= 38·12°
Mean Temperature	38·92°	40·91°	42·04°	= 40·62°

Such are the results of two exceptional winters. The Manx winter is, however, remarkable for its mildness, its

Digitized by Google

mean temperature amounting to 42·10°, which is higher than five out of the six south coast counties—namely, Kent, 39·3°; Sussex, 40·0°; Hants, 40·7°; Dorset, 40·9°; Devon, 42·0°; and Cornwall, 44·8°; the last being the only county the mean temperature of which exceeds that of the Isle of Man; the mean temperature of these six counties being 41·3°, or 1·7° colder. Added to the mild temperature and comparative freedom from snow and frost, which characterise the Manx winter, the visitor should remember, when hesitating between going abroad and going to the Isle of Man, that in the latter he need not fear either the cholera, the mistral, or earthquakes, and that in sunniness it ranks next to the Channel Islands, which are the sunniest parts of the British Isles, as shown by Mr. A. W. Moore, M.A., M.H.K., in his "Manx Note-book." Let him remember, too, that the Isle of Man lies within 54° lat. N., or more than three degrees further north than the south coast, and he will then be prepared, after what has been said, to purge his mind of the fallacy that the winters must necessarily become colder and the summers less genial the further one travels from the south to the north.

THE HOSPITAL SUNDAY FUND.

ON the 6th inst. a public meeting was held at the Lambeth Palace Library in support of the hospitals and medical charities in Lambeth participating in the Hospital Sunday Fund. The meeting was the first of a series of public meetings to be held during the next fortnight in eight different districts of London for the purpose of arousing public interest in the pecuniary needs of the hospitals. The chair was occupied by Lieutenant-General Fraser, M.P., at the opening of the proceedings, in the temporary absence of the Archbishop of Canterbury, who arrived, however, shortly after the meeting began, and then took the chair. Viscount Lewisham moved the first resolution: "That this meeting pledges itself to use every endeavour to arouse the inhabitants of this district of London to the importance of maintaining the hospitals and medical charities in the utmost efficiency. In furtherance of this object it urges the clergy and the ministers of religion to point out the advantage of giving to the Hospital Sunday Fund, owing to the nominal cost of so collecting funds for hospitals, and to make an earnest appeal to the people to so increase their contributions as to secure that the whole sum collected shall not be less than £100,000." The Rev. Arthur Jephson seconded the resolution, and the Rev. Hermann Gallaney, speaking on behalf of the Hebrew community in Lambeth, supported it. The resolution having been carried, Mr. Henry C. Burdett, chairman of the Executive Committee, moved the second resolution:—"That this meeting regrets to learn that the expenditure and liabilities of the hospitals and medical charities in this district in the year 1886 exceeded the ordinary income by more than £10,000, and pledges itself to increased exertion with the view of preventing any like deficiency during the current year." The Rev. Newman Hall seconded this resolution, and the chairman having supported it, it was carried unanimously. A vote of thanks to the Archbishop of Canterbury for presiding and granting the use of the library for the purpose of the meeting brought the proceedings to a close.

On the 7th inst. a meeting was held at the Paddington Vestry Hall, the Rev. W. Abbott in the chair. Amongst those present were Baron Ferdinand de Rothschild, Mr. Henry C. Burdett, Hon. Henry Noel, and Mr. E. Parker Young. After some introductory remarks from the chairman, Baron Ferdinand de Rothschild, in a very able speech, setting forth the needs as well as the merits of our general hospitals, proceeded to show how very small was the proportion of the amounts collected from year to year in aid of the Hospital Sunday Fund (£40,000) in so large and wealthy a centre as London, and contrasted the enormous amount spent in pleasure and fancy articles of dress, especially of the Jubilee novelties of the present year, showing that by comparatively little self-denial ample means might be forthcoming to furnish even more than the £100,000 now wanted to free our medical charities from debt. The Hon. Henry Noel seconded the resolution, which was identical with that moved at the other meetings. Mr. Henry C. Burdett and Mr. E. Parker Young proposed and seconded the second resolution, which was similar to the second resolution proposed on the 6th inst. at the Lambeth meeting, and which was unanimously adopted, as was also a vote of thanks to the chairman, and to Mr. Michelli, secretary of St. Mary's Hospital, and Mr. Ryan, secretary of Queen Charlotte's Hospital, the hon. secretaries, who had been at the trouble of organising the meeting.

On the 8th inst. a meeting was held at the Hampstead Vestry Hall, Haverstock-hill. Lord William M. Compton occupied the chair, and was supported by Sir Sydney H. Waterlow, Sir Joseph Fayrer, the Rev. Sherrard B. Burnaby, M.A. (vicar of Hampstead), the Rev. Dr. Kennedy, Mr. R. F. Horton, M.A., Mr. J. S. Fletcher, J.P., Mr. G. H. Powell, J.P., and others. The receipt of letters was announced from the Marquis of Lorne, Lord Cranborne, Lord Robartes, and others, expressing regret at inability to be present. The Rev. S. B. Burnaby moved the first resolution, which pledged those present to use every endeavour to arouse the inhabitants of Hampstead and north-west London to the importance of maintaining the hospitals and other medical charities in the utmost efficiency, and called on the clergy and other ministers of religion to earnestly appeal to their congregations to assist in securing a collection of not less than £100,000 for the Hospital Sunday Fund, against the £40,390 collected last year. Sir Sydney Waterlow seconded the resolution, and it was carried unanimously. Sir Joseph Fayrer moved, and Mr. R. F. Horton seconded, a resolution pledging the meeting to increased activity on behalf of the local hospitals and dispensaries, which was also carried unanimously, and a cordial vote of thanks to Lord W. Compton for presiding terminated the meeting.

A meeting was held on the 8th inst. at the Rink Hall, Blackheath, Mr. Henry Green in the chair. Mr. Fell Pease, M.P., Sir Edmund Currie, Admiral the Hon. F. Egerton, Mr. G. C. Whiteley, the Rev. Rhodes Bristow, D. Reith and C. Wilson, and Mr. Burdett being the speakers. It was pointed out that the south-eastern district, with upwards of 1,000,000 inhabitants, contained but 486 hospital beds, of which only 374 were occupied in 1886 owing to a want of funds. The apparent deficiency between income and expenditure amounted to £2800, but the actual deficiency was quite £8000. The crowded districts of Camberwell, Deptford, and Bermondsey, with Greenwich and Lewisham, were very inadequately supplied with hospital accommodation and the necessity of increasing the size of the Miller Hospital was insisted upon by several of the speakers. Mr. Reith urged that if Birmingham, which had collections in seventy places of worship, could collect £5000 on Hospital Sunday, then London, with 2000 contributing congregations, was able to raise on the same average at least £150,000 every year. Mr. Burdett, referring to the co-operation and presence of Lord Salisbury, the Duke of Cambridge, Lord Rosebery, the Archbishop of Canterbury, Lord Randolph Churchill, and other eminent men, regretted that the local members of Parliament for Greenwich and the district did not apparently care enough for the sick and suffering of south-east London to follow so excellent an example as that set them by their leader the Prime Minister. He was glad to see Mr. Whiteley at the meeting, and to be able to report that in every other district of London the local members of Parliament were doing their utmost to help the hospitals. There was a statement made by Mr. Bristow in the local press to the effect that Hospital Sunday injured the Royal Kent Dispensary and was not an unmixed blessing to the hospitals. This was not the fact, for whereas the Royal Kent Dispensary received on an average £73 per annum from church collections in the ten years preceding the establishment of Hospital Sunday, during the first ten years of the fund the grant to the dispensary averaged £130, and during the last three years it was over £140 per annum. As to its effect on the hospitals as a whole, it had been shown by the production of the actual figures that allowing for the increase in population and for all other circumstances, Hospital Sunday had benefited the London hospitals to the extent of £20,000 per annum, by which the voluntary incomes of these institutions had increased during the years it had been established in the metropolis. In other words, whereas the expenditure of all the hospitals had increased to the extent of one farthing per head of the population, the income had increased to an amount equal to one penny per head, showing a clear gain in available funds of three farthings per head of the entire population. The meeting was a genuine success, and the speeches provoked more than ordinary interest. A vote of thanks to the chairman closed the proceedings.

)YAL COLLEGE OF SURGEONS IN IRELAND.

. MEETING of the Fellows, presided over by Sir William kes, was held on Saturday, the 4th inst., to receive the ual report of the Council, and for the consideration of ain notices of motion by Mr. Thomson and Sir Charles neron.

he tenure of office and election of vice-president was t discussed, consequent on a resolution of the Council sed last March, and a motion that it should be adopted the College was proposed by Mr. W. Stoker. At the gestion of Mr. Chaplin, however, it was resolved that the retary to the Council should be instructed to call the ention of the in-coming Council to the matter, and that leeting of the College should be called to consider the olution.

Ir. Thomson's notice of motion then came on for discus-n. It was as follows:—"That, having regard to the erests of medical education in Dublin, it is desirable to inish, as far as possible, the number of proprietary ools, and that, with a view to carrying out this principle, e an instruction to the Council to take such steps as may necessary to effect, in the first instance, an amalgamation ween the College School and the Carmichael College of licine." In the course of his speech Mr. Thomson stated willingness to withdraw the word "proprietary" in his olution. There was a debt of £6500 on the Carmichael lege, the interest of which it was intended should be ally defrayed by the professors of both medical schools. Kidd thought if amalgamation took place the teachers uld be better paid, and the classes of students in at-dance better looked after. He moved that the words uitable terms" be added to the motion, which was uiesced in. Mr. Bennett spoke against the proposal and sidered that the fusion of the two schools named could be carried out with advantage. Mr. Macnamara thought range that in the report of the proceedings of the Council Fellows did not receive the information they were tled to in respect to this matter. There was, he said, a ority of the Council against the scheme, and a protest been made against the proposed amalgamation by a large ority of the professors of the College itself. It was also trary to the Supplemental Charter to bring in a great ny others connected with a school outside the College lf. Mr. Barton declared his opinion that it would a mutual advantage to both schools to become amal-nated. The increase in the number of professors would gradually reduced in course of time. Mr. W. J. ker, Mr. Jacob, and Mr. Fitzgibbon also spoke in favour the motion. Mr. Hamilton asked why the Fellows the College should force upon the professors of the ege the burden of debt of £6500. He was always osed to amalgamation. Three years ago the scheme, n brought before the Council, had been negatived, and second occasion a similar result had occurred. He had red, if a majority of the College professors were not osed to the scheme, not to take any action in the ter; but if otherwise, he resolved to throw himself heart soul into the opposition. He thought if the competi-from the extramural schools were removed it would end to the advantage of medical education. He believed reason the College school fell away was because the nders" and demonstrators had been discouraged; but ad not the slightest doubt of its ultimate success. A ion took place, and on the votes being counted a slight onderance was shown on the side of those objecting to motion, and by request the names were taken down. rs. Robinson and Jacob were appointed by the President crutineers, and as a result it was found that 27 voted and 30 against Mr. Thomson's motion, which was rdingly declared lost by the President.

C. Cameron's motion, in consequence of the lateness he hour, was adjourned to Monday, when it came on for deration. The motion was—"That the College regret ailure of the attempt to unite the Colleges of Physicians Surgeons and the Apothecaries' Hall for the purpose of ng examinations. The College is of opinion that a attempt to effect this tripartite combination should be made, the Medical Council having recognised the hecaries' Hall as a medical corporation; and should an apt again fail, the College considers that the Council ld, if possible, form a combination with the Apothecaries' Hall." Sir C. Cameron pointed out that the Apothecaries' Hall was now a legal licensing body, and showed that a moderate fee, some £10, would be the cost of their diploma. They were capable of giving a registrable diploma, which was eligible for Poor-law vacancies and for the services, &c. It was extremely unlikely that the College of Physicians would join with the Apothecaries' Hall, and it was therefore of great importance in the interests of medical education that the College of Surgeons should form a combination with that body. Dr. Kidd seconded the motion, which was opposed by Mr. Chaplain, who moved as an amendment that the last clause in the resolution be struck out. This amendment was seconded by Sir George Porter, but on being put to a division it was lost, and Sir C. Cameron's motion was adopted.

THE REOPENING OF THE PUMP ROOM AND BATHS AT LEAMINGTON.

ON the 1st inst. the Royal Pump Rooms, Leamington, which had been closed for several months for purposes of repair, improvement, and renovation, were formally re-opened by the Right Hon. A. W. Peel, Speaker of the House of Commons. The proceedings commenced with a luncheon at the new Town Hall, at which upwards of 300 were present, including a large number of representatives of the medical profession from the neighbourhood and various midland towns. After the luncheon a procession was formed from the town hall to the Pump Rooms, where there was a large assembly of spectators to witness the opening ceremony.

The Speaker, who presided, in opening the proceedings spoke of the pleasure it gave him to take part in that large gathering, and said he trusted that the reopening of these baths would greatly contribute to the prosperity of the borough. Having alluded to the curative properties of the Leamington waters, he expressed the hope that those persons who were in the habit of recruiting their health by having recourse to the continental spas would not forget that they might procure as much benefit by the use of the waters at home.

On the motion of Dr. T. W. Thursfield, a hearty vote of thanks was given to the members of the medical profession who had come from various parts of England to assist in the proceedings. The compliment was acknowledged by Dr. Garrod, who argued at considerable length that the most beneficial results often followed the judicious employment of saline baths and drinks.

Mr. Oliver Pemberton combated the popular idea of sending patients away to foreign spas while there was adequate provision at home. Dr. Burney Yeo also responded. Dr. Eardley Wilmot proposed a vote of thanks to the visitors. The motion was adopted, and the High Sheriff and Sir A. Hodgson responded. On the proposal of the Mayor of Leamington, a cordial vote of thanks was given to the Speaker for his attendance that day, and the Speaker having acknowledged the compliment, the proceedings closed.

In the evening the baths were thrown open for public inspection, and were visited by many hundreds of the inhabitants of the town.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF THE INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

Diphtheria in the City of Winchester, by Dr. PARSONS.—Winchester has more than once been inspected by officials from the Local Government Board. But it is satisfactory to note that, whereas when Mr. Power visited the city in 1877, on account of the prevalence there of fatal diarrhœa, water was derived partly from wells, there was no system of sewers, cesspools being in general use, and cesspit privies were discharging into drains, Dr. Parsons now reports that a sewerage scheme has been carried out, that cesspools have been abolished, that the Water Company's service is all but

Digitized by Google

general, that an infectious hospital, disinfecting stove, and mortuary have been provided, and that a great improvement has been effected in the house property. Winchester has certain defects which attach to the locality in which it is placed. Much of the city stands on an alluvial flat, the alluvial deposits containing an impervious bed of peat, upon the configuration of which subsoil water is held up as in a cup. But the disease which has recently been under investigation seems to have had no connexion either with these special physical circumstances or with any of the remaining sanitary defects. The diphtheria, which, together with suspicious sore-throats, attacked eighty-three persons between April, 1886, and March, 1887, was scattered in all parts of the city, the high-lying chalky slopes suffering in common with the low-lying alluvial bed; the attacks were found at each extreme of the social scale; and in many of the houses attacked there was no obvious sanitary defect. In nineteen of the thirty-nine houses attacked, the first case was a child attending day-school, and in several instances there was in the street opposite the house affected a sewer ventilator which was stated to have caused offensiveness. No such defect was, however, detected at the date of Dr. Parsons's inspection. Milk could be set aside as the cause of this disease, and, after careful investigation, it appeared that the spread had been mainly brought about by reason of contact with a number of ill-defined attacks of sore-throat, which, though from a clinical point of view they may not be described as diphtheria, are yet etiologically of the same nature. A number of these cases are given, one group showing that the paralysis of the muscles of accommodation in the eye was the only symptom apparent, and that the cases were sufficiently numerous to have led one schoolmistress to imagine that the eye affection itself was of an infectious character. In a case of three adults it was found that one man with sore-throat was given some drink in the same mug with two other men. Both of the latter were, within two or three days, attacked with genuine diphtheria, one having paralysis of the soft palate.

The Sanitary State of the Okehampton Rural District, by Dr. BLAXALL.—The sanitary state of this district was inquired into in connexion with the administration of the Public Health Act in the locality. Many of the dwellings were found to be of a very inferior character, having stone floorings, and otherwise affording evidence of dampness. Water supplies, except in certain specified places, are exposed to excremental pollution, and in some instances supplies still remain in use, although they have brought about enteric fever, and are derived from sources which continue to be open to suspicion. Certain towns and villages have sewers, but even in these cases such matters as ventilation and flushing need attention. Pig-keeping and excremental and other nuisances also obtain to a considerable extent in the district. In April, 1886, parochial committees were appointed by the sanitary authority, but Dr. Blaxall could not learn that any action had resulted from this step. Neither the work of the medical officer of health nor that of the inspector of nuisances is held to have been what the sanitary circumstances of the district should have demanded; and the remuneration of the former is held to be altogether inadequate to secure such services as are called for. On the whole, this district does not bid fair to do much towards removing those conditions of ill-health which so freely obtain throughout a large portion of its area.

Spilsby Rural District.—The death-rate for this district during 1886 was 14·83 per 1000. The rate quoted in our issue of May 28th was the average of the preceding twelve years.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 4861 births and 3452 deaths were registered during the week ending June 4th. The annual rate of mortality in these towns, which had been 20·3 and 20·4 per 1000 in the preceding two weeks, declined last week to 19·5. During the first nine weeks of the current quarter the death-rate in these towns averaged 20·5 per 1000, and was 1·5 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 12·8 in Derby, 13·2 in Portsmouth, 13·7 in Brighton, and 15·3 in Leicester. The rates in the other towns ranged upwards to 25·9 in Newcastle-on-Tyne, 26·4 in Blackburn, 27·0 in Norwich, and 30·5 in Manchester. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 532 and 522 in the preceding two weeks, further declined last week to 521; they included 252 from measles, 143 from whooping-cough, 44 from scarlet fever, 34 from diarrhœa, 26 from diphtheria, 22 from "fever" (principally enteric), and not one from small-pox. The death from any of these zymotic diseases was registered during the week in Derby, whereas they caused the highest death-rates in Birkenhead, Norwich, and Manchester. The greatest mortality from measles occurred in Brighton, Sheffield, Liverpool, Oldham, Salford, Newcastle-upon-Tyne, Birkenhead, Norwich, and Manchester; and from whooping-cough in Birmingham, Bolton, and Plymouth. The 26 deaths from diphtheria in the twenty-eight towns included 15 in London, 2 in Liverpool, 2 in Manchester, and 2 in Oldham. No death from small-pox was registered in London or in any of the twenty-seven large provincial towns. Only four cases of small-pox were under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease; one new case was admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 289 and 333 in the preceding two weeks, declined again last week to 264, and exceeded by one the corrected weekly average. The causes of 84, or 2·4 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Portsmouth, Brighton, Preston, and in six other smaller towns. The largest proportions of uncertified deaths were registered in Leicester, Nottingham, and Salford.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns which had been 21·3 and 22·6 per 1000 in the preceding two weeks, declined to 19·8 in the week ending June 4th; this rate exceeded, however, by 0·3 the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 15·[illegible] in Aberdeen and 17·8 in Perth, to 21·2 in Greenock and 22·[illegible] in Leith. The 495 deaths in the eight towns last week showed a decline of 69 from the number in the previous week, and included 32 which were referred to whooping-cough, 5 to scarlet fever, 4 to measles, 4 to diarrhœa, 3 to diphtheria, 2 to "fever" (typhus, enteric, or simple), and not one to small-pox; in all, 50 deaths resulted from these principal zymotic diseases, against 72 and 82 in the preceding two weeks. These 50 deaths were equal to an annual rate of 2·0 per 1000, which was 0·9 below the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had steadily increased in the preceding four weeks from 31 to 43, declined again last week to 32, and included 11 in Glasgow, 10 in Edinburgh, 5 in Dundee, and 4 in Leith. The deaths from scarlet fever, measles, diarrhœa, and "fever," showed a considerable decline from recent weekly numbers. Three deaths from measles and 1 from diarrhœa occurred in Glasgow; and 2 of the few cases of scarlet fever were returned in Edinburgh. The 3 deaths from diphtheria included 2 in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 126 and 109 in the preceding two weeks, further declined last week to 102, but exceeded the number returned in the corresponding week of last year by 12. The causes of 64, or nearly 13 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 25·4 and 24·1 per 1000 in the preceding two weeks, further declined to 21·4 in the week ending June 4th. During the first nine weeks of the current quarter the death-rate in the city averaged 28·7 per 1000, the mean rate during the same period being but 18·5 in London and 19·6 in Edinburgh. The 145 deaths in Dublin last week showed a further decline of 18 from the numbers in the previous two weeks; they included 10 which were referred to measles, 4 to scarlet fever, 3 to "fever" (typhus, enteric, or simple), 3 to whooping-cough, 1 to diarrhœa, and not one

Digitized by Google

ther to small-pox or to diphtheria. Thus the deaths re-
lting from these principal zymotic diseases, which had
creased in the preceding four weeks from 19 to 27, de-
ined again last week to 21; they were equal to an annual
te of 3·1 per 1000, the rates from the same diseases being
9 in London and 2·1 in Edinburgh. The fatal cases of
easles, which had been 8 and 17 in the previous two weeks,
clined again last week to 10. The deaths from scarlet
ver exceeded the average numbers in recent weeks; while
ose from "fever" corresponded with the number in the
receding week. The deaths of infants showed a consider-
le increase, while those of elderly persons were fewer than
any previous week of this year. Five inquest cases and
deaths from violence were registered; and 30, or more than
fifth, of the deaths occurred in public institutions. The
auses of 24, or more than 16 per cent., of the deaths
gistered during the week were not certified.

THE SERVICES.

WAR OFFICE.—Army Medical Staff: Surgeon-Major
rank Pout is granted retired pay, with the honorary rank of
rigade-Surgeon (dated June 4th, 1887); Surgeon-General
rchibald Henry Fraser has been granted retired pay (dated
lay 18th, 1887); Surgeon-Major William Taylor, M.D., has
een seconded on appointment as Surgeon to his Excellency
he Commander-in-Chief in India (dated Dec. 26th, 1885).

ADMIRALTY.—The following appointments have been
ade:—Inspector-General of Hospitals J. Breatky, to Haslar
ospital; Staff Surgeon B. Renshaw, to the *Sylvia;* Staff
urgeon R. W. Williams, to the *Defiance;* Surgeon W. E.
piller, to the *Duncan;* Surgeon N. H. Atock to the *Nelson;*
nd Surgeon John F. Bate, to the *Sealark* (dated May 23rd).

ROYAL ARTILLERY MILITIA.—9th Brigade, North Irish
ivision: Surgeon-Major A. Skipton resigns his commission
lated June 4th, 1887).

RIFLE VOLUNTEERS.—2nd Ayrshire: Acting Surgeon R.
irvan, M.D., to be Surgeon (dated June 4th, 1887); Surgeon
. Girvan, M.D., is granted the honorary rank of Surgeon-
Iajor (dated June 4th, 1887).—1st Dumbartonshire: John
Vylie, M.B., to be Acting Surgeon (dated June 4th, 1887).—
st Volunteer Battalion, the South Staffordshire Regiment:
cting Surgeon Thomas Edgar Underhill, to be Surgeon
lated June 4th, 1887).—6th (West) Suffolk: Edgar George
arnes, M.D., to be Acting Surgeon (dated June 4th, 1887);
nd Arthur Worlledge Aldrich, to be Acting Surgeon (dated
une 4th, 1887).

Correspondence.

"Audi alteram partem."

THE HEREDITY OF TUBERCULOSIS.

To the Editors of THE LANCET.

SIRS,—The leading article on this subject in THE LANCET
f last week induces me to offer the following remarks:—

The breeds of domesticated animals afford the best oppor-
unities to trace the working of heredity, both physio-
ogical and pathological. The practice of breeding in-and-in
s the one chief reason why heredity is so marked in cattle.
Vithout entering on the abstract differences between an in-
erited disease and an inherited liability to fall into disease,
shall state an unambiguous case of inherited tubercle that
appened lately within my experience. Being in the
orth of Scotland last Christmas, I went one day to see
relative who has a farm. He happened to mention
hat if I had come a day earlier I might have assisted
t the post-mortem examination on a diseased calf. From
what I learned on inquiry, I was led to request that the
ody might be dug up (it was merely buried temporarily
nder a mound of earth owing to the intense frost in the
ground), and I was rewarded with a spectacle of bovine
ubercle such as I had not seen before. All the serous
surfaces of the abdomen were thickly studded with enormous
essile and stalked masses of rounded and flattened tubercles,
ike thick spelter buttons, with reddish lines of vessels on
he grey surface. The calf was eight months old, and had
ever thriven, although it had lived through the best season
of the year. The new growths, which were like flat sarco-
mata of dense texture, or like fibromata, as bovine tubercles
often are, had every appearance of being a slow or chronic
formation. The evidence of heredity was conclusive. This
calf, as well as four others on the farm, was after a short-
horn bull, which had begun to waste in like manner, and
had been destroyed in his third year; and my informant
assured me that the interior of the carcase presented just
the same appearance as in the calf at that moment under
our eyes. The bull had been purchased, when a calf, at the
annual sale of young stock by a breeder of short-horns well
known in the county. The four other calves by the same
sire were in good condition; one of them had shown some
joint weakness, which is occasionally an early indication of
tubercle. The dam of the diseased calf, a short-horn cow
without pedigree, did not appear to be ailing in any way.
There is nothing unusual in this case, which came under my
notice quite casually; veterinary surgeons are constantly meet-
ing with facts of the same kind, and they seem to regard the
tuberculous diathesis as part of the strain or breeding of such
animals. Those of them who practise in breeding districts are
well aware that the complete dispersal of a pure-bred herd is
not unfrequently owing to the subtle invasion of hereditary
tubercle among the stock from in-and-in breeding, and to
the impossibility of eliminating it without a general
clearance. Such of us as have not assented to Dr. Koch's
upsetting doctrine of the parasitism of tubercle, do not
find any great difficulty in dealing with the facts of
heredity, or in finding a place for them in our synthetic
judgment of the disease as a whole. I would respectfully
ask those who are still uncommitted by any declaration on
the point in question to consider once more on how
slender a thread of experimental evidence Dr. Koch's allega-
tion of "pure culture" of the tubercle bacilli rests. The
New Sydenham Society has done a great service to the
English profession in including Dr. Koch's memoir in the
volume of essays recently translated under Mr. Watson
Cheyne's editorship. Dr. Koch remains, I believe, still the
only experimenter who has carried out the whole procedure
from first to last, including the separation of the bacilli
from the tuberculous substance in which they occur, and
the inoculation of animals with the parasites in a state of
purity, as he thinks. The evidence is thus to be found
within narrow limits, and the crucial part of the evidence
is all contained in a few sentences of the volume above
mentioned. I am, Sirs, your obedient servant,

London, June 6th, 1887. C. CREIGHTON.

"PLACENTA PRÆVIA."

To the Editors of THE LANCET.

SIRS,—The case of "Placenta Prævia" recorded in THE
LANCET by Dr. B. Walker is another interesting illustration
of the true physiological treatment which I have advocated
for the last forty years, and which abundant clinical
experience has substantiated. "Blood was flowing freely,
and complete placenta prævia was present. Introducing the
hand," says Dr. Walker, "into the vagina, *and detaching the
placenta*, a vertical presentation was found, and with two
fingers in the uterus and the right hand on the abdomen,
combined version, after Braxton Hicks's method, was quickly
and easily performed and a foot brought down, thus
plugging the cervix and causing the hæmorrhage to cease,
the whole being done in five minutes. The woman was left
comfortable. . . . . The delivery was completed spon-
taneously after twelve hours."

I submit that the just commentary upon this case is that
the hæmorrhage ceased because the placenta was detached
from the lower or dangerous zone of the uterus, which
allowed the os and cervix to expand; that the subsequent
bipolar turning, although the case ended happily, was not
clearly the cause of the arrest of hæmorrhage by plugging;
that unless the uterus contracted to force the breech upon
the lower segment of the uterus the breech could not act as
a plug, since it was not kept in contact with the bared
surface by being dragged down upon it; and that experience
amply proves that, if there be contraction, this is enough to
arrest the hæmorrhage.

Dr. Walker holds, as Sir James Simpson held, that the life
of the child was of secondary importance. In this I quite
agree. But was the child's life incompatible with saving
that of the mother? When the head presents, it is surely
better to dilate the cervix with my hydrostatic bags, which

Digitized by Google

plug even better than the child's breech, provoke uterine activity, and give the opportunity either for spontaneous delivery by the head or by the forceps, either of which gives a much better chance of saving the child without compromising the safety of the mother. The combined method of turning comes in admirably in some cases, but it is only an application of this proceeding. It cannot be regarded as constituting by itself the rational treatment of placenta prævia. I am, Sirs, yours truly,

Harley-street, June 6th, 1887. ROBERT BARNES.

"A SUGGESTED IMPROVEMENT IN ETHER INHALERS."

To the Editors of THE LANCET.

SIRS,—Under the above heading, Mr. Rickard W. Lloyd, in an interesting communication in your issue of May 28th calls attention to a possible danger of Clover's ether inhaler, and he suggests that the anæsthetiser should possess and use a number of indiarubber bags to minimise the risks of transmitting disease from one patient to another.

Mr. Lloyd, as, I believe, all who administer ether will allow, has put his finger upon the weak part of Clover's inhaler, which is the bag. Unless the apparatus is in constant use the bag gets out of order. In hospital practice, and in the practice of surgeons who have much operating, it is tolerably easy with care to maintain the bag in good order; but even then holes will mysteriously and unaccountably appear in it. But the general practitioner, who has to let his apparatus lie on the shelf for an unknown length of time, too often finds, when he requires it on an emergency, that the bag has stuck together, and can only be opened up at the cost of tearing, or has already several perforations in it, and then sticking plaster or other tinkering expedients have to be used to render the apparatus temporarily workable. Regarding the carbonic poisoning which the bag of Clover's apparatus causes in greater or less degree, I refrain from expressing an opinion, as I have heard it condemned on the one hand as a danger, and extolled on the other as a virtue, by competent authorities. I would, however, ask those who approve this carbonic acid poisoning if, supposing they were about to inhale ether, they would give instructions to the anæsthetiser to allow their own blood to become carbonised, or whether they would not, on the contrary, prefer that their blood should be as free as possible from this noxious gas, and consequently the action of the right side of the heart be impeded as little as possible? Deaths from ether are unfortunately not unknown, and it behoves us to adopt every measure to render its administration safe as well as effective. For some time I have been making trials with an apparatus which Messrs. Mayer, Meltzer, and Co. have constructed to my order, which, whilst doing away altogether with the bag, retains all the useful features of Clover's apparatus. The patient never re-breathes expired air, and the danger pointed out by Mr. Lloyd cannot therefore occur. My trials and experiments are not yet complete, but I hope that the firm mentioned may soon be able to offer to the profession an efficient and handy inhaler which will surmount Mr. Lloyd's difficulties even more satisfactorily than his own suggestions do.

I remain, Sirs, your obedient servant,

NORMAN PORRITT,

May 31st, 1887. Hon. Surgeon, Huddersfield Infirmary.

THE HOVE INFECTIOUS HOSPITAL.

To the Editors of THE LANCET.

SIRS,—As it is your practice in all disputed cases to give facilities for "the other side" to obtain a hearing, I trust that you will permit me, as one of the laymen whom you condemn in your article of May 28th for directing public attention to the alleged defects at the Hove Sanatorium or Infectious Hospital, to offer a few remarks by way of explanation. In the first place, these "laymen," whilst claiming no great or extensive sanitary knowledge, have had considerable experience in hospitals and hospital management. General Shute, C.B., both in the Crimea and in India, learnt much practical knowledge in field and other hospitals, and, without being an "expert," now possesses valuable experience on this subject. I am no novice in hospital management, having for many years been interested and concerned in hospital government. At the present time I am one of the house committee of the largest hospital in London. Therefore, feeling ourselves qualified to form an independent opinion, we ventured to criticise the report of the local medical officer, who stated that "all the requisites of an institution of the kind were all that can be desired." I have no intention of giving in detail the deficiencies to which we ventured to direct attention; it will be sufficient for me to say on this occasion that we complained of defects in the arrangements (owing to the peculiar site on the downs), of defects in the condition of the building, and of deficiencies as regards certain sanitary appliances. We are confident that these defects would be admitted by competent and independent sanitary authorities. We are anxious only for the truth as to the facts and for efficiency as to the hospital, and we desire competent inspection, and fully believe that we shall thereby obtain confirmation of our criticisms. We have a duty to our constituents which we are anxious to fulfil. A large sum of public money has been expended on this hospital; our constituents are rated for its repayment. They deserve an efficient hospital for their outlay, and, conscientiously believing that at the present time the hospital is not in a satisfactory condition, we ventured to raise our voices against the optimistic report of the medical officer, feeling sure that the public attention thus aroused would ensure the removal of the defects of which we had complained. In conclusion, I may add that the cost of remedying these defects would only amount to an inconsiderable sum of money. Under the circumstances, I trust that you will regard our conduct as deserving of praise and not of blame, and that you will assist us and not add to our difficulties in rendering this hospital thoroughly efficient.

I am, Sirs, yours truly,

Brighton, June, 1887. ALFRED G. HENRIQUES.

*** We took no exception to a mere endeavour to remedy such defects as may exist in this hospital, but we do not admit that some of the conditions which were alleged to indicate defects are faults at all. Mr. Henriques brought forward statements calculated to damage the hospital in the minds of the general public, and thus to hinder the very object for which it was erected. He is also reported to have objected to its ventilation, to have said that "the arrangements.....were the very reverse of what such an institution should possess".....and "were as bad as they could be"; and he spoke of its "fatal objections." We deny the accuracy of such statements, and, in answer to them, we would quote the following authorities, who have at least equal knowledge with Mr. Henriques as to what are the requirements of an infectious hospital. Dr. Ewart, chairman of the Brighton Sanitary Committee, says: "The ventilation is excellent"; and he adds that "with proper care and management.....your building.....will prove a great benefit to the town." Dr. Kelly, medical officer of health to West Kent, says: "On the whole, the building seems to have been carefully planned, and to be well adapted for use as an infectious hospital." Such statements alone suffice to show how unwise was the wholesale condemnation of the hospital which was made public last month.—ED. L.

THE VALUE OF DRUGS.

To the Editors of THE LANCET.

SIRS,—The remark of Sir William Gull at the recent meeting of the Medical Council has elicited considerable correspondence on the value of drugs in the treatment of disease. I have no doubt he never intended that his remark should be taken literally, but only that it should be a strong blow at the system of empirical treatment pursued principally by dispensing chemists over the country. Every medical practitioner must have noticed how much faith the uneducated place in a bottle of medicine, and must also be aware how some dispensing chemists and all quacks pander to this taste. There is in this way many a shilling wasted in medicine that might have been well spent in a good beef-steak or coal for the fire. Medicine is seldom the most important part in the treatment of disease, and it is of the utmost importance for us at all times to impress this upon our

Digitized by Google

ients. I expect that few men give the large quantities of dicine that was common some years ago, and the simplicity prescriptions is an important step in the right direction. r these things the profession and the public are indebted men, such as Sir William Gull, who advocate a rational de of treatment, and who have done so much to abolish at system of rough treatment now even dying out of the terinary profession. I have no doubt Sir Wm. Gull will ieve in the use of medicine properly administered as icerely as any of us, but it is only leading men like him o can take a stand with general advantage for truth and mmon sense.—I am, Sirs, yours faithfully,

Hawick, June 6th, 1887. JOHN R. HAMILTON, M.D., &c.

OYAL COLLEGE OF SURGEONS: THE PETITION.

To the Editors of THE LANCET.

SIRS,—At last the draft of the petition of the Council of e Royal College of Surgeons (Eng.) has appeared, and, as as to be expected, it contains none of the reforms demanded th by Members and by a considerable proportion of the llows of the College. There is no provision made for an nual general meeting of Fellows and Members, and none r the admission of Members to the Council or to a share its election. After nearly 5000 Members of the College ve expressed their opinion that such alterations as those e have just cited are desirable, and after their petition to at effect has been presented to the Privy Council, it seems ite impossible that the College Council can obtain such a harter as that for which it is now petitioning. At all ents, the Members having, over a month ago, lodged their tition with the Privy Council, and having asked to be ard in this matter before any new Charter is conferred, e can assure the Council of the College that every endea- our will be made by the Members to secure the reception the Privy Council of an influential deputation in their half. We are, Sirs, your obedient servants,

W. C. STEELE, } Hon. Secs.
June, 1887. W. A. ELLIS, } Assoc. M.R.C.S.

THE PROFESSION AND THE PEERAGE.

To the Editors of THE LANCET.

SIRS,—There is a proud self-respect in our profession hich forbids us, individually or collectively, claiming any ublic recognition of our efforts to promote the public good. irtue is, no doubt, its own reward; but the area of useful- ess frequently bears some proportion to the power and fluence of those desirous of being useful, and social power, ke any other force, does not lose in momentum by having filter through all strata of society from an exalted osition. The immediate object of this metaphorical state- ent is to give utterance, through the influential medium of our journal, to a notably widespread feeling in the pro- ession that something should be done to call attention in he proper quarters to the desire of many of its members hat, in the celebration of the Jubilee of our gracious overeign, a medical peerage should not be conspicuous y its absence. It will not be fruitful to inquire why his country should be singular in excluding from the anks of its nobility a body of citizens who cannot on any rounds be considered socially inferior to many of those who re periodically raised to the Upper House. Nor is it need- ul that the services medicine and surgery have rendered to he State and to mankind during the last fifty years should e enumerated at length. They are well known and reco- nised by the Faculty, and the State and individuals have o excuse for ignoring them. I feel sure that I speak for any when I say that no honour would be appreciated ore highly, or received more enthusiastically by the pro- ession, than that which could be done it in the person of ne or more of its representative members, by their being aised to the peerage of the United Kingdom. I trust hat your influential and judicious advocacy may render a edical peerage one of the essential features of the Queen's ubilee. I am, Sirs, yours truly,

June 6th, 1887. ASCLEPIAD.

To the Editors of THE LANCET.

SIRS,—An opportunity for Her Majesty is afforded by the pproaching Jubilee to show her appreciation of the valuable ervices rendered by our profession to herself, to the members of the Royal Family, and to all classes of Her Majesty's subjects, including the very poorest. It would be a most graceful acknowledgment of such services for special honour, and that honour a peerage, to be conferred on the chief representatives of the medical and surgical professions.

I am, Sirs, yours truly,

June, 1887. A COUNTRY SURGEON.

THE COLLEGE OF SURGEONS' EXAMINATIONS.

To the Editors of THE LANCET.

SIRS,—I have no desire to increase the terrible ink-shed with which Mr. Heath's strictures on the College of Surgeons' examinations have deluged your columns. But, as one who has just emerged from the fiery ordeal of the combined examinations, I trust you will permit me to state the case from the successful candidate's point of view.

The cases cited by your correspondent, Mr. F. J. Smith are only such as constantly occur within the experience of every student. The "good man" sometimes go down like ninepins, and the "duffers" are successful. Why? Simply because the latter answer the questions which the former are ignorant of. Granted that a good man is now and then plucked, my own experience shows that in nine cases out of ten he well deserves his fate. If, as Mr. Smith says, every man has his weak point, he should do his best to remedy it, or else not complain if he is given six months in which to do so. The examiners can only judge of him as they find him. Mr. Smith appears to think his third and fourth cases have been hardly used. But I submit that if a man who is shaky on such a subject as fracture of the base is allowed to write "F.R.C.S. Eng." after his name, the diploma will soon cease to be regarded as the highest surgical qualification in the world. On the first occasion on which I presented myself for the final M.R.C.S., I was referred for six months, and, as is usual and quite natural, thought myself very unfairly treated. But, on reviewing the various incidents of the examination during the period thus afforded me for mature reflection, I was obliged to own that I had been asked straightforward questions, to which I could only return unsatisfactory answers. Curiously enough, I also came a cropper over cranial fractures, or, as Mr. Smith would put it, "the examiner had found my weak point, and had pressed me on it to the total exclusion of all other subjects." I have heard of a man who was never able to pass because the examiners would ungenerously persist in asking him the very things he did not know. For my own part, I have always felt that the gentlemen who did me the honour of examining me were the heads of the profession which I, a raw recruit, was endeavouring to enter. It would be invidious for me to mention the names of individual examiners, but I may say that, treating them with respect, I have ever received kindness and consideration. I say emphatically, after two experiences, that I consider the final M.R.C.S. examination to be honestly and fairly conducted; and, in conclusion, that I have never known a so-called "good man" to be referred unless, by his own admission, he had been guilty of some breach of that submission which, as a student, it was his duty to accord to his examiner.

I am, Sirs, your obedient servant,

June 4th, 1887. L.R.C.P., M.R.C.S.

MANCHESTER.

(*From our own Correspondent.*)

OWENS COLLEGE.

ON Saturday last the members of the professorial staff of the College, with members of the Council and other friends, met at the College to do honour to Sir Henry Roscoe, who has lately severed his connexion with it as a teacher after having for so many years presided over and brought the chemical department to its present efficient state. Unfortunately Sir Henry Roscoe was prevented by severe indisposition from leaving his house on that day, so that the ceremony of presenting an address and unveiling a portrait of their late colleague subscribed for by the professors was somewhat shorn of its interest. Professor Greenwood gave an appropriate address, briefly reviewing the work of Sir Henry during his thirty years connexion with the College, and unveiled the portrait, which was then presented in the

Digitized by Google

name of the professors to the Council, being received by Mr. Oliver Heywood on behalf of the latter body. Amongst other matters which Sir Henry has recently been inquiring into during his recent short stay here has been the question of the sale of butterine, making himself familiar by personal inquiry and investigation with all the trade details of the same, with a view to the proposed legislation on the subject. Amongst "the trade" of the district much adverse criticism has found its way into the public press concerning the provisions of the Bill now before Parliament, dealers asserting that the article known as butterine is a good and wholesome food, and that the Adulteration of Food and Drugs Act provides ample protection to purchasers if properly put in force.

JUBILEE EXHIBITION.

The Jubilee Exhibition opened last month by the Prince and Princess of Wales is proving a great success. The chemical, sanitary, and dietetic exhibits are of considerable interest from a medical point of view, and a short description of some of them will find a place in the near future in these columns. Amongst "the machinery not in motion," a railway invalid carriage will no doubt attract the notice of the profession. It is sent by the Lancashire and Yorkshire Railway Company, and is fitted up with every convenience for the removal of a patient with the least possible amount of discomfort. A small fixed bedstead is in one corner, with movable table, rests, and supports, a small ante-room for friends or attendants at one end, and a lavatory, &c., at the other.

HOSPITALS.

The proposed extension of the Fever Hospital belonging to the Royal Infirmary is meeting with considerable opposition, and the Newton Heath Local Board, in whose district the hospital is situated, at their last meeting peremptorily called upon the infirmary to suspend all further building operations until such time as the plans, &c., had been approved by them, which plans they at present decline to pass. The neighbouring borough of Salford at their last council meeting had a discussion on the following proposition: "That by way of commemoration of Her Majesty's Jubilee, the council be recommended to assist the Health Committee in the erection of a new hospital for infectious diseases, to be called the Victoria Hospital." It was suggested that a town's meeting be called to consider the subject, but the motion was eventually lost. It is thought that the proceeds of the old fever hospital in Cross-lane—i.e., £21,000—should provide a new hospital without any special appeal.

HEALTH REPORT FOR 1886.

The officer of health for the city has just published his annual report for last year. Again Manchester shows an exceedingly high death-rate, it being 24·69 per 1000 per year. The mortality from scarlet fever was double that of the previous year, 188 deaths being recorded from it, notwithstanding the removal to hospital of a large proportion of the sufferers. From small-pox no death occurred. The officer of health devotes some considerable space to the question of air impurity, and considers that the Health Committee should now devote much of its energies in endeavouring to render the air more pure, in the crowded streets and alleys alike, and the inside of many of the worst dwellings, where proper ventilation is impossible and cubic space per occupant sadly deficient. At the present time both scarlet fever and measles are exceedingly prevalent. The death-rate for the first quarter of the present year from the seven common zymotic diseases was equal to 3·8 per 1000 per annum.

June 7th.

CITY ORTHOPÆDIC HOSPITAL.—The thirty-sixth anniversary festival in aid of the funds of this hospital was held on the 8th inst., the Duke of Grafton presiding. Since the institution has been in existence 52,000 cases of deformities have been treated, the number of patients who received relief during last year being over 3000. In the course of the evening the secretary announced subscriptions and donations amounting to between £900 and £1000.

THE annual festival dinner in aid of the funds of the North London Consumption Hospital will be held on the 15th inst., at the Langham Hotel, under the presidency of Mr. F. D. Mocatta.

LIVERPOOL.

(From our own Correspondent.)

A SATURDAY NIGHT AT THE ROYAL SOUTHERN HOSPITAL.

THIS hospital is situated in the midst of what is known as Toxteth-park—a great misnomer, being composed largely of streets, many of which are of a character the very reverse of sanitary, and tenanted by a very low class of inhabitants. As a consequence of this, Saturday night is always more or less a busy night at the hospital, as Saturday, June 4th, was one of the busiest ever known since the hospital was opened. From early on Saturday night till early on Sunday morning about fifty cases were admitted and treated, two proving fatal: one was that of a man who fell down in the street in a fit, was found lying insensible by a policeman, and on reaching the hospital was found to be dead; the other was that of a child three months old, which was taken to the hospital by its mother, expiring in her arm on the way there. In addition to these, a woman was admitted with a wound in the thigh, a man with a fractured leg, a woman suffering from severe burns, a woman with serious injury to the back, and a man with severe injuries to the head.

BEQUESTS TO LOCAL HOSPITALS.

Under the will of the late Mrs. Anna Maria Heywood, widow of the late Mr. John Pemberton Heywood of this city, the Royal Infirmary and the Northern Hospital, Liverpool, each receive legacies of £1000. It is expected that the local medical charities will benefit largely under the will of a former wine merchant in this city, who has bequeathed the bulk of his estates, amounting to a very large sum, to local charities.

HOSPITAL SUNDAY AND SATURDAY.

It was recently proposed to change the date of Hospital Sunday from the second Sunday in January to some Sunday in May. Endeavours were made to ascertain the opinion of the clergy and ministers of all churches and chapels wherein collections had been made as to the desirability of a change of date; and in the event of the change being deemed advisable, then as to which month the collection should be transferred to. The replies were so evenly balanced that it was thought safer to leave matters as they are. The Hospital Saturday Fund already exceeds £2000, as more contributions have yet to be announced.

THE LATE BISHOP OF SODOR AND MAN.

The announcement of the death of the Right Rev. John Rowley Hill, Lord Bishop of Sodor and Man, was received in this city with much surprise. The late Bishop was a man of very great physical strength, and up to within a few days of his death presented the appearance of a man in the prime of robust healthy manhood, his age being fifty-one. For some days before his death he had been indisposed, which had induced him to give up engagements in Sheffield as well as in the Isle of Man and to remain in London. On Friday, the 27th ult., he suddenly grew worse, became unconscious about noon, and died the same evening. The reports as to the cause of his death differ. It was at first stated to be congestion of the liver; another and later account in the *Isle of Man Times* states that "he had for some time suffered from kidney disease, and a few days before death there were evidences of the presence of diabetes. The more immediate cause of death, however, is considered to have been extravasation of blood on the brain." His mental powers would appear to have been unaffected almost up to the last, and he preached in the very church where only a fortnight later his remains were taken previously to interment.

POISONOUS REFUSE.

From time to time cases occur of wholesale poisoning, fortunately seldom fatal, arising from the very objectionable practice which prevails here of depositing among shop and warehouse refuse nuts of a poisonous nature. Some years ago a number of children were poisoned by eating Calabar beans, one boy dying. Within the last few days a number of children were taken to the Royal Southern Hospital suffering from symptoms of poisoning in consequence of their having eaten some nuts which they found in a heap of rubbish. The nuts were stated to be croton nuts. The children suffered from acute pains in the stomach, accompanied by nausea and vomiting, but recovered.

(*From our own Correspondent.*)

ALBUMINURIA IN THE APPARENTLY HEALTHY.

At the last ordinary meeting of the Royal Society of Edinburgh a paper on the Discharge of Albumen from the Kidney in Healthy People was read by Professor Grainger Stewart. The paper contains the results of an extensive research carried out in relation to varied classes of the community. Professor Stewart comes to the conclusion that in the community generally the average of those who have albuminuria is about 30 per cent.; in military life the proportion is larger than amongst civilians, and with advancing years there is a marked increase in the proportion. In all classes he finds an increased number showing albumen after breakfast, as compared with what obtains before that meal. While healthy moderate exercise, as in the weekly march-out of the garrison, decreases the number in whom it is present, excessive muscular exercise, as seen in fatigue duty, largely increases the proportion of men showing albuminuria. Several other phases of human activity have been investigated in the same way, and yield most interesting results. Some of the general conclusions at which Professor Stewart arrives are the following:—That there is no sufficient proof that albuminuria is a normal condition in the human subject, but that it is a much more frequent phenomenon in the apparently healthy than was formerly supposed; that it increases in frequency as life advances, and is more common in those who lead laborious lives than in others; that moderate exertion decreases the phenomenon, whilst excessive work produces an increase, as does also cold bathing in certain individuals; and, finally, that the existence of persistent albuminuria is not *per se* a sufficient ground for the rejection of a proposal for life insurance. The paper, which was richly illustrated by tables, giving a complete analysis of the results, was very favourably received by the Society, and its author was congratulated upon the comprehensive and valuable nature of his research.

THE PRESENCE OF BACTERIA IN FISH.

At the same meeting of the Royal Society a paper on the existence of Bacteria in Living Fish was presented on behalf of Professor Ewart. A variety of species of micro-organisms are constant inhabitants of the majority of fresh-water and sea fish alike, the skate, dogfish, and some other species being, however, exempt. A considerable number of organisms may be present in the blood, lymph, and peritoneal cavity without any apparent interference with the vitality of the animal. Under a variety of depressant conditions the number of these bacilli increases: thus starvation, confinement in aquaria, and a rapid, though moderate, rise of temperature produce this effect, and the increase, if considerable, is accompanied by symptoms of languor and, in many cases, the death of the fish. The exact species of bacilli discovered have not as yet been classified; experiment shows, however, that they are not of ordinary putrefactive varieties, while the clinical evidence equally excludes them from the group of pathogenic microbes.

THE MEDICO-CHIRURGICAL SOCIETY.

At the recent meeting of this Society some interesting cases illustrating the condition of word-blindness were exhibited by Dr. Byrom Bramwell, who gave a valuable clinical demonstration of the main symptoms in two of his patients. Mr. A. G. Miller showed two patients who made an excellent recovery after operations for the relief of intracranial suppuration. Dr. Foulis exhibited a new and useful apparatus for the irrigation of the bladder, and a new form of obstetric forceps. A paper was read upon some Poisonous Products of an unusual nature present in Human Food, detailing the results obtained by Drs. Philip and Hare in a recent case of poisoning that occurred in Carlisle. Dr. Philip succeeded in separating from some ham, the material suspected, an extract poisonous to frogs, and producing symptoms in the human subject suggestive of irritant poisoning, and resembling those observed in the large number of patients who suffered after the ingestion of portions of the ham in question. Microscopic examination showed the presence of micrococci in the ham, but no bacilli were discovered resembling those present in the Wellbeck case which occurred in 1880, where poisonous ham was found to be the cause of the outbreak. A special meeting of this Society is to be held early in July, to discuss the subject of scarlet fever in relation to the recent epidemic in Edinburgh, and specially with regard to questions of the etiology of the disease now exciting such great interest.

Edinburgh, June 7th.

DUBLIN.

(*From our own Correspondent.*)

ROYAL COLLEGE OF SURGEONS.

THE contest for the vice-presidency of the College which took place on Monday last excited unusual interest, as it was known that it would be a close one. Mr. Fitzgibbon, the successful candidate, polled 126 votes, against 102 obtained by his opponent, Mr. Croly. As regards the Council, all the outgoing members who offered themselves were re-elected, with the exception of Mr. Story; while two new members have been added—viz., Mr. Frazer and Mr. Kendal Franks. More than a month since, when writing on this subject, I mentioned Mr. Franks as certain of success, and the result has justified my expectation. An unusual compliment was paid Mr. Frazer by electing him on his first attempt, and he will, I am convinced, prove a formidable opponent to Mr. Meldon in the contest for the vice-presidency next year. The votes at the meeting last Monday were the highest ever recorded, and numbered 230. At the annual meeting of the College on Saturday an animated discussion took place in reference to the proposal for amalgamation between the Carmichael College and the College School. The matter is referred to more fully in another column, and I only allude to it here to remark that the debate would not have suffered by the admixture of a larger proportion of the elements of courtesy and toleration on the part of some of the speakers than was manifested on the occasion. By the recent rules of the Council the examiners in anatomy and surgery, who were appointed on the 31st ult. for the ensuing year come under different arrangements as regards their emoluments, which has caused considerable dissatisfaction to those most interested in the matter. Previously the eight examiners in these subjects received equal remuneration, but now two examiners only in anatomy and two in surgery will as a rule be actually employed. The two other examiners in these subjects, whom I shall style assistant examiners, are only expected to act during the sickness or absence of the others, and to examine candidates for fellowship. It follows that almost all the fees from candidates will go to the acting examiners; and, on the other hand, the assistant examiners will neither have much honour or profit. For, taking the average annual number of Fellows admitted to examination, the remuneration of each assistant examiner will probably not exceed from £10 to £15 per annum. I believe it is not at all improbable that one, if not more, of these assistant examiners will shortly resign his post.

DUBLIN HOSPITALS COMMISSION.

It is authoratively stated that no steps will be taken by the Government, at least for this session, to carry out the recommendations of the Dublin Hospitals Commission. This is a result which probably will not cause much surprise, a feeling existing to a very general extent that such would be the case.

HOSPITAL FOR INCURABLES.

An appeal is being made by the governors for funds to carry out a design formed to extend the usefulness of this excellent institution. It is contemplated to add a new wing for the treatment of patients suffering from cancer and phthisis. It will be called the "Victoria Jubilee Wing," and I am in a position to state that his Royal Highness Prince Albert Victor, on his approaching visit to Dublin, will lay the foundation stone of this addition to the hospital.

THE JACOB TESTIMONIAL.

An address with a purse containing £500 was presented to Dr. A. H. Jacob at the College of Surgeons on Monday last. The address was read by Dr. Mapother, and Dr. Jacob having made a suitable reply, the proceedings terminated. The address, it may be mentioned, was signed by over 400 medical practitioners.

I am informed that Sir William Stokes and Prof. Edward Hamilton have been appointed coadjutor examiners in Surgery for the Apothecaries' Hall of Ireland.

(From our own Correspondent.)

PARALYSIS FROM EARTHQUAKE ELECTRICITY.

A COMPLETE account of the effects of the Nice earthquake from a medical point of view has yet to be written. In the meantime, facts of the highest interest are recorded by different observers. I have seen several cases of pulmonary disease which had been progressing satisfactorily up to that time, and in which the agitation attending the disturbance inflicted an irrecoverable shock to the nervous system. One lady has come under my care whose menstrual period, just commencing when the first shock occurred, was immediately checked. A month later the catamenia were restored by uterine faradisation, the discharge, which had not been preceded by the usual premonitions, occurring within a few hours of the application. Similar phenomena have been recorded by others. Dr. Onimus relates a case of nervous disturbance (Société de Biologie) of unusual interest. The subject was a strong vigorous man, not easily impressionable and incapable of deceit. He was at the time in charge of a fort. There were, it will be remembered, three distinct commotions, the strongest at six, another soon after, and a third, much weaker, at nine o'clock. The patient was sending a telegraphic message, and, happening to have two points in contact with the metal of the transmitting apparatus, felt a violent shock, and lost consciousness for ten minutes. During the remainder of the day he felt giddy and weak, but has no recollection of *phosphènes* at the occurrence of the shock. Two months later he complained of constant headache and fibrillary contractions in the muscles of the limbs. The right arm was paretic, and the extreme weakness was confirmed by the dynamometer. Besides tremor and painful localisations along the median nerve, there was a considerable decrease of sensibility, the finger-tips scarcely recognising a separation of twelve millimetres between the points of the compass. The paralysis of the face was on the left side, and consisted of ptosis, accompanied by blepharospasm. This crossed or alternate paralysis is what is seen constantly as a result of a powerful electric shock; but in this case the symptoms have been more serious and persistent. At the present time there is little if any improvement. The reappearance of Dr. Onimus, whose communication was received with the greatest attention, was hailed with pleasure by the Society, the more so as it has been reported of late that the health of the eminent electrician had been failing.

EPIDEMIC PNEUMONIA.

M. H. Rondet of Lyons has given particulars of two epidemics of *fluxion de poitrine* that have come within his experience. The first occurred at Fleurien-sur-Saône, a little village about ten miles north of Lyons. The disease made its appearance on March 29th, 1882, the weather being cold and misty, and the epidemic was confined to the inhabitants of a house jointly occupied by the school teachers and rural police and their visitors. Of ten patients attacked four died. The second outbreak was at the vagrants' depôt at Albigny, which comprises a population of from 630 to 650 individuals, divided into two categories, those who have entered voluntarily and those who have been sentenced to a short imprisonment for begging or vagrancy. The epidemic lasted five months, and was extremely fatal, fifty-nine deaths occurring in seventy cases. An attentive study of the conditions of development of the disease showed that its intensity and duration were in proportion to the vitiation of the atmosphere and the defects of the sanitary surroundings. The contagion was most dangerous in the dark, unventilated apartments, and there was no doubt as to the infectious nature of the disease.

ACUTE GLANDERS.

Dr. Dhoste, the medical officer of the steamer *St. Germain*, running between St. Nazaire and Vera Cruz, states that one of the passengers, a Spaniard, who embarked in perfect health at Havannah, began to show symptoms of acute glanders five days later. No treatment was of any avail, and the patient was landed in a dying condition at Santander.

SANITARY PRECAUTIONS FOR MARSEILLES.

The town council of Marseilles has passed a resolution that it is desirable for the troops returning from Tonkin and other colonies where epidemic diseases are constant to be landed at the quarantine stations of Port Cros and Bazan, instead of Marseilles. It is probable that the different administrations concerned in the matter will acquiesce in this view, and disembark the men, in the first instance, at some point in the island of Hyères.

GASEOUS RECTAL INJECTIONS.

At the congress of the delegates from the learned societies held last week at the Sorbonne the question of gaseous enemata came under discussion. M. Lamallerée said that, judging from his own personal experience, gaseous injections were inefficacious when there existed cavities, but in other stages of the disease (phthisis) they were useful. To be successful no precaution should be neglected. The improvement obtained consists in suppression of the fever, sweats, and oppression; the general health becomes more satisfactory, and the stethoscopic signs are modified. M. Lamallerée stated that he had been able to infect chickens with tubercle by mixing the expectoration of bacillary phthisis with their food, but not when the sputa came from patients under the treatment. In other diseases of the lungs this method gives rapid and durable results.

Paris, June 8th.

AUSTRALIAN NOTES.

(From our own Correspondent.)

MALPRACTICES IN NEW SOUTH WALES.

As a sequel to the case of Dr. Russell of New Zealand, which I referred to in my last letter, I have two more cases in New South Wales to relate. Encouraged apparently by the very easy way in which abortion-mongering is regarded in the colonies, this crime seems to be increasing in frequency. A case of the kind has recently occurred at Redfern, a suburb of Sydney, where a Dr. Sabatowski (with a German degree) had operated on a young single woman, and made a laceration of the uterus six inches in length, death ensuing within twenty minutes of the operation. The person in question escaped terrestrial justice by committing suicide, taking poison out in the bush, where his body was subsequently found. Another man, this time without a qualification, has introduced a novelty in gynæcological science by performing craniotomy with "a chisel, a screwdriver, and a pair of pincers, borrowed from a blacksmith." The woman died, but as the "obstetrician" charged only 30*s.* for the operation nothing more could reasonably have been expected. No inquiry was held, and reasons have been asked from the coroner for such non-action by the Minister of Justice.

A QUEENSLAND UNIVERSITY.

The first steps towards the formation of a university were inaugurated by a meeting of gentlemen summoned by the Chief Justice to consider the question, when it was decided to draw up a petition to the Government—to be signed by doctors, clergymen, lawyers, corporations, schoolmasters, &c.—to take steps to carry out that object by the necessary grants, &c.

QUEENSLAND BOARD OF HEALTH.

This board have been trying to make the public believe they are an energetic body, by going as a deputation to the Colonial Secretary and asking for executive powers to be granted to them, as they at present only possess the power of "making recommendations." The Minister, however, pointed out to them that they had made such very little use of what power they had, that he did not feel inclined to recommend their being granted any more. As a fact, it is a decrepit and useless board, and would be most beneficially replaced by an experienced, scientific, well-paid medical officer of health imported from England, with special sanitary knowledge; and this is what will eventually have to be done.

TOWNSVILLE (QUEENSLAND) HOSPITAL.

The authorities of this institution have recently decided to appoint a resident surgeon-superintendent, in place of the paid visiting surgeon. This, as the metropolis of the future colony of "Northern Queensland" (the separation of which is bound, in common justice to the North, to ensue), is an important town and the centre of a very large tract of country, the hospital thus offering great advantages of practice; and I expect the appointment will be warmly competed for.

Digitized by Google

SYDNEY UNIVERSITY.

The following gentlemen have been appointed examiners for the third examination for the degree:—In Medicine: C. M'Kay, M.D. Surgery: A. Renwick, M.D. Midwifery: C. K. M'Kellar, M.D. Medical Jurisprudence: H. N. M'Laurin, M.D. Psychological Medicine: Sir A. Roberts, M.R.C.S.

SYDNEY HOSPITAL.

This hospital is still in a most unsatisfactory condition. The present wooden structure was put up as a temporary building ten years ago, and has long been condemned as utterly dangerous in case of fire. The late Premier, in a note which he left for his successor at the late dissolution, spoke of the patients in it as liable to "wholesale destruction" in such an event. The new site is considered by the Government unsuitable; hence the delay.

DEATH FROM CHLOROFORM.

A man died in the Sydney Infirmary recently whilst being operated on for a crushed hand, under the influence of chloroform. Three drachms were used in about five minutes, administered by means of a perforated leather mask containing a piece of sponge. One minute after the inhaler had been removed the heart stopped. Hypodermics of ether and galvanism were resorted to, but without avail. Dr. Knaggs, President of the New South Wales branch of the British Medical Association, said that, in his opinion, fatty degeneration of the heart was the cause of death.

POISONING BY ORNAMENTAL BISCUITS IN MELBOURNE.

Several children have suffered from all the symptoms of irritant poisoning lately after eating ornamental biscuits. These were found on analysis to contain arsenic and copper in the colouring matter, and the manufacturers, at the instance of the Central Board of Health, were fined £20 and costs.

In Melbourne two hundred and thirteen cases of typhoid were reported from March 1st to 24th, of which fifty-eight were fatal.

THE NEW ZEALAND POISONER.

Hall, who was convicted of the murder of his father-in-law on the clearest evidence, has escaped capital punishment by a legal technicality. The conviction for murder has been quashed on appeal, on the grounds that part of the evidence on which he was convicted of the murder of his father-in-law had been used at the previous trial, when he was convicted of the attempted murder of his wife, and was therefore inadmissible. Thus, by a legal quibble, a scoundrel has escaped justice, than whom no more cruel or cold-blooded Brinvilliers ever existed. What little consolation there is to be got out of this case lies in the fact that his "life" sentence for the attempted murder of his wife stands good, and no Minister of the Crown is ever likely to commute his sentence.

BRISBANE MORTALITY.

Out of 120 deaths for the month of February seventeen were from typhoid. As Dr. Thomson pointed out at the last meeting of the Board of Health, the mortality among young children in Brisbane is abnormally high. Of course the late weather has been against them, for the rains have been continuous for the last three months, and floods have occurred everywhere.

Dr. A. Ross has been returned for Molong at the general election, Dr. W. C. Wilkinson for The Glebe, and Dr. W. R. Cortis for Bathurst. Of course, Drs. M'Kellar and Creed still hold their seats in the "Lords."

The Hon. C. K. MacKellar, M.L.C., has just left Sydney on a visit to the old country, and (if he finds it possible) to America. He has done well, professionally and politically, out here, and is worth welcoming as a very creditable representative of the profession in Australia.

The medical men of Launceston, Tasmania, have unanimously protested against the sewage being drained into the river. Typhoid is prevalent there.

March 31st.

THE DEER IN RICHMOND PARK.—On the 8th inst. it was reported to the Richmond magistrates that there had been no further slaughter of deer in Richmond Park, and that the district was free from contagious disease. There is every indication that the epidemic of rabies among the deer is now being fast stamped out. The number of animals killed is estimated at nearly 200.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT an ordinary meeting of the Council held on Thursday, June 9th, the Minutes of the Library Committee on the 18th ult., as the report from that committee, were read; and it was agreed that, as recommended by the Library Committee, the vacant librarianship be filled up by the appointment of a librarian specially educated for such office, and that the vacancy in the office be advertised, and candidates invited to send in their applications by a given date; also that the salary of the librarian be £400 per annum, to be increased, after one year of service, to £500 per annum, provided the person appointed shall perform his duties to the satisfaction of the Council.

The third report, dated the 2nd inst., from the Committee on the Extension of the College Premises, relating to an addition to the building of the library and the appointment of a pathological curator, was read, approved, and adopted, subject to further consideration and discussion at the extraordinary meeting of the Council, which is to be held on Monday, June 27th (when the motion as to the disposal of the Erasmus Wilson bequest comes on for consideration).

A letter from Mr. Lund, resigning his position as member of the Court of Examiners was received, and his resignation accepted, with an expression of great regret at the illness which was the cause of it. The election of examiner to fill the vacancy will take place at the Council meeting on June 27th.

A letter, dated the 6th inst., from Mr. John Marshall, reporting, as the representative of the College, the proceedings of the General Medical Council during their late session, was read, received, and entered on the Minutes, and the best thanks of the Council were given to Mr. Marshall for his services as the representative of the College on the General Medical Council.

The following gentlemen were nominated for election in July as professors and lecturers to the College: Messrs. Bryant, Hulke, Stewart, Warner, Lockwood, Jessop, E. Nettleship, Marcus Gunn, Sutton, J. Priestley Smith, W. Arbuthnot Lane, and W. Watson Cheyne.

The President stated to the Council that he had received from Mr. J. Talfourd Jones of Brecon a portrait of Jenner, which he offered to the acceptance of the College. This was accepted, with the best thanks of the Council to Mr. Talfourd Jones for the same.

A letter of the 14th ult., from Mr. James Bankart of Exeter, a Fellow of the College, was read, enclosing a memorial to the Council on the subject of the new regulations of the Examining Board in England, and their influence on sutdents at provincial hospitals. This was referred to the Committee of Management to report to the two Colleges.

Three further memorials forwarded by Mr. Benjamin Bryan, and received on the 2nd inst., in opposition to the proposals contained in the memorial forwarded by Dr. Wilks relating to the disposal of the Erasmus Wilson Fund, were acknowledged.

A motion by Mr. Macnamara, "that it be referred to the President and Vice-Presidents to consider and report to the Council as to the propriety of rearranging the lectures annually delivered in the College, and of making them more serviceable to the profession," was agreed to.

Mr. Hutchinson gave notice of the following motion:—"To arrange for the delivery, by members of the Council or others, of special lectures, expository of the pathological preparations in the museum of the College."

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following Members, having passed the Final Examination for the Fellowship on the 25th, 26th, and 27th ult., were, at a meeting of the Council held on Thursday last, duly admitted Fellows of the College:—

Carr, J. W., M.B. Lond., Bloomsbury-square; diploma of Membership dated Oct. 24th, 1884.
Hadley, Wilfred J., L.S.A., Cavendish-rd., Clapham; Nov. 16th, 1883.
Hare, Evan Herring, L.S.A., Mortlake-road, Kew; August 2nd, 1876.
Hatch, W. Keith, M.B. Aberd., Pall Mall; August 3rd, 1876.
Heatherley, Francis, Newman-street; January 28th, 1885.
Hewkley, F., L.S.A., Cazenove-rd., Stoke Newington; Nov. 21st, 1881.
Hughes, Edgar Alfred, Onslow-gardens; January 24th, 1884.

Digitized by Google

James, David Philip, L.R.C.P. Lond., Tenby, South Wales; Nov. 16th, 1871.
Lawrence, Laurie Asher, L.S.A., Mansfield-gardens; Jan. 22nd, 1884.
Lund, H., M.B. Cantab., Whalley Range, Manchester; July 30th, 1885.
Richmond, C. E., L.S.A., The Infirmary, Warrington; Jan. 28th, 1876.
Robinson, H. Betham, M.B. Lond., York-crescent, Lower Norwood, July 20th, 1883.
Spencer, Walter G., M.B. Lond., St. Barthol. Hosp.; Aug. 3rd, 1885.
Tubby, A. H., L.R.C.P. Lond., Studley-rd., Clapham; July 29th, 1884.

Four other candidates passed the examination, but being under the legal age (twenty-five), the grant of their diplomas was postponed. Thirteen candidates failed to reach the required standard, five of whom were referred for six months and eight for one year.

At the same meeting the following Member, who passed the Final Examination in May, 1885, was also admitted a Fellow:—

Braddon, W. Leonard, Upton-on-Severn; diploma of Membership, dated April 23rd, 1884.

The following gentlemen, having passed the necessary examinations for the diploma, were at a meeting of the Council on the 9th inst. admitted Members of the College:—

Cockerton, Herbert, Cambridge Lodge, Lower Tooting.
Dean, Henry Percy, Dromore, Anson-road, Tufnell-park.
De Renzi, A. Castriot, Chaplain's House, H.M. Prison, Wandsworth.
Harris, Worsley John, Bennett-park, Blackheath.
Johnson, Harold Jossé, Bishopsgate-street.
Kirkpatrick, Randolph Fernhill, Bolingbroke-road.
Westbrook, Richard Talbot, Guy's Hospital.
Whicher, Alexander Hastings, Westcombe-park.
White, Charles Percival, Furnival's-inn.

SOCIETY OF APOTHECARIES.—The following gentlemen, having satisfied the Court of Examiners as to their knowledge of the Science and Practice of Medicine, Surgery, and Midwifery, received certificates entitling them to practise as Licentiates of the Society on June 2nd:—

Cotes, Digby Francis Baynes, Purton, Swindon, Wilts.
Morris, Edward Walter, Southern-hill, Reading.
Peachey, George Charles, Albany-street, Regent's-park.
White, Thomas Dawe, Wallerton-road, W.

On the same day the following gentlemen passed the Primary Examination:—

Atkins, Sidney Ernest, St. Bartholomew's Hospital.
Best, William Jenner, London Hospital.
Jessop, Arthur Rowland, Guy's Hospital.

The examination in Arts of the Society of Apothecaries was held in the hall of the Society on the 3rd and 4th inst., when there were 201 candidates. The class lists will be published, it is understood, early next week. The third examination in Arts of the Society of Apothecaries for this year will be held on the 2nd and 3rd days of September next, and the fourth examination in Arts is fixed for the 2nd and 3rd days of December next.

THE Jubilee Extension Fund in connexion with the Aberdeen Royal Infirmary amounts now to upwards of £22,924.

ÆSCULAPIAN SOCIETY.—The annual dinner of this Society took place on Friday, June 3rd, in the Holborn Restaurant. The meeting was a very successful one.

VACCINATION GRANT.—Mr. William Rowlands, of the Sephton District of the West Derby Union, has been awarded the Government grant for successful vaccination.

MR. J. O'DONOVAN, F.R.C.S.I., of Mount Haigh, Kingstown, has been placed on the Commission of the Peace for co. Dublin.

ROYAL SOCIETY.—The second *soirée* of the season, that to which ladies are admitted, was held on Wednesday at Burlington House. There was a large and distinguished company present.

ON the 2nd inst. an athletic festival, in aid of the building fund of the Great Northern Central Hospital, was held at Tufnell Park, its organisers being the police of the Y Division and tradesmen of the district.

CREMATION.—The Geneva Town Council is agitating for the institution of a crematory furnace for the Canton, on the scale of that so successfully worked at Milan. M. Empeyta, the chief mover in the matter, has put forth a defence of the practice against common objections. Mineral poisons, he maintains, are as easily detectable after cremation as after burial, while premature cremation is avoided at Milan by sending the corpse to the *ustrinum* not sooner than eight days after death.

HOSPITAL SATURDAY.—The street collection on behalf of the London hospitals takes place to-day (Saturday).

AN Oriental bazaar in aid of the funds for building a wing for the accommodation of out-patients at the East London Hospital for Children at Shadwell was opened on the 2nd inst. at the Westminster Town Hall by the Duchess of St. Albans.

SANITARY INSTITUTE OF GREAT BRITAIN.—At an examination, held on June 2nd and 3rd, seventy-seven candidates presented themselves—nine as local surveyors and sixty-eight as inspectors of nuisances. Of the former class four satisfied the examiners, of the latter class forty-four were approved.

THE epidemic of measles at Grantham, which has now reached the workhouse children, is supposed to have been brought into the town by travelling hawkers who attended the recent fair. The Town Council are discussing the advisability of inspecting the vans of these persons before again allowing them access to the town.

CONSULTATIVE RELATIONS BETWEEN HOSPITALS AND PROVIDENT DISPENSARIES. — The Medical Attendance Organisation Committee has appointed a sub-committee to consider a plan for bringing "hospitals and provident dispensaries into consultative relations." The sub-committee consists of Sir T. Spencer Wells, Bart., Dr. F. H. Alderson, Mr. W. G. Dickenson, Dr. J. Grey Glover, Dr. W. M. Ord, Dr. Gilbart Smith, Dr. J. C. Steele, Dr. Walter Smith, Dr. W. E. Steavenson, Mr. W. Bousfield, and Lieut.-Col. Montefiore.

THE WATER SUPPLY OF THE CITY.—At the last meeting of the City Commission of Sewers, a report of the Streets Committee, recommending that a tender of £1750 be accepted for constructing an artesian well at the artisans' dwellings in the City, was adopted. The work, it will be remembered, is being projected by way of an experiment to ascertain whether pure water can be cheaply supplied to the City independently of the water companies, whose charges have been the subject of complaint.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At a meeting of the Fellows on Monday last, the following office-bearers were elected for the ensuing year:—President: Anthony H. Corley. Vice-President: Henry Fitzgibbon. Secretary: William Colles. Council: G. F. Kidd, William Colles, Sir Charles Cameron, Edward Hamilton, Robert McDonnell, Sir William Stokes, William J. Wheeler, Sir George Porter, J. Kellock Barton, E. H. Bennett, Philip Crampton Smyly, W. Stoker, Rawdon Macnamara, A. Meldon, William Elliott, William Carte, Samuel Chaplin, William Frazer, and Kendal Franks.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—The general meeting of the members of this Society was held on the 20th ult., when the fourteenth annual report was read and adopted. During the past year nine meetings, with an average attendance of forty-five, have been held, twenty-one new members have been elected, twelve have resigned, and the Society now numbers 214 members. The library has been considerably increased, and three additional microscopes have been purchased. The financial report was satisfactory. The following were elected office-bearers for the ensuing year:—President, Mr. Edward Atkinson; Vice-Presidents, Dr. Cameron and Mr. McGill; Treasurer, Dr. Clifford Allbutt; Hon. Secs., Dr. Jacob and Mr. Edward Ward; Librarian, Dr. Barrs; and Auditor, Dr. Braithwaite.

THE INTERNATIONAL CONGRESS ON ALCOHOLISM.—At Antwerp, which in 1885 was the scene of the last Congress on this great question of public health, it was arranged that the next should be held this year at Zurich on Sept. 9th and 10th. The permanent committee are organising for the occasion an exposition of everything bearing on alcoholism. For example: tables and diagrams of different countries indicating the consumption of alcohol per head of the population; the proportion of persons annually undergoing imprisonment per 100,000 of the inhabitants; the annual proportion of suicides and of lunatics; the annual outlay on alcoholic drinks compared with that incurred for articles of prime necessity; plans of asylums for inebriates; specimens of non-intoxicating beverages; and comparative regulations of the various temperance societies, with statistics of their working.

Digitized by Google

IN honour of Her Majesty's Jubilee, it has been decided by the promotors that the procession annually organised in the East-end of London on Hospital Saturday shall this year be conducted on a more extensive scale than usual.

EXHIBITION AT WIESBADEN.—A scientific exhibition will be connected with the 60th Congress of German Naturalists and Physicians to be held in Wiesbaden from the 15th to the 24th of September. It will be strictly scientific, not mercantile, and its purpose will be to show at a glance the latest and most perfected instruments and apparatus which have been placed at the disposal of science and medicine in the last few years. The following groups will form part of it:—Surgery, physical diagnosis and therapeutics; ophthalmology, gynæcology; laryngology, rhinology, and otology; orthopædics, dentistry, chemistry, instruments of precision, with subdivision for microscopy; instruments and apparatus aiding instruction in natural history, geography, equipment for scientific travel, photography, anthropology, biology and physiology, hygiene, electro-therapeutics and neurology, and pharmacology.

MEDICAL NOTES IN PARLIAMENT.

Pure Beer.

IN the House of Commons on the 7th inst., in reply to Mr. Bonsor, the Chancellor of the Exchequer stated that since the deputation eighteen samples of beer, purchased of various publicans chosen by the hon. member for Suffolk (Sudbury Division), had been carefully analysed at the laboratory at Somerset House, and he was able to inform the House that in no single case had any adulteration, noxious or otherwise, been detected, but, on the contrary, the beers were genuine and of high alcoholic strength. This statement fully corroborated the correctness of the view maintained by the Board of Inland Revenue.—Mr. Quilter asked whether the right hon. gentleman could inform the House if the samples analysed had been obtained by the officers of excise of the district, who would be presumably well known to the publicans, or were purchased over the bar by some of the public in the ordinary course of business.—The Chancellor of the Exchequer understoood that the samples had been arranged for by the hon. member himself.—Mr. Bonsor wished to state that he had nothing to do with procuring the samples, except to indicate the localities. He believed that they were procured through the officers of excise.—The Chancellor of the Exchequer said that, if the hon. member wished it, further inquiry should be made.—Mr. Quilter hoped that the right hon. gentleman would ascertain whether or not these samples were obtained by the officers of excise.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

FAULKNER, W. COOKE, M.B., C.M.Ed., has been elected Medical Officer to the Second District of the Eastbourne Union.

GELSTON, JOHN S., L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer for the Sapiston District of the Thetford Union.

GODFREY, GRAHAM P., L.R.C.S., L.R.C.P.Ed., has been appointed Assistant Medical Officer for the Workhouse of the Sheffield Union.

HARRISON, WALTER, D.M.D. Univ. Harv., L.D.S. Roy. Col. Surg. Eng., has been appointed Honorary Dental Surgeon to the Throat and Ear Dispensary, Brighton, vice W. Lloyd Poundall, resigned.

HOWARD, WILFRED, M.R.C.S., L.R.C.P. Ed., has been appointed Medical Officer for the Third District of the Depwade Union.

HUGHES, EDGAR A., M.R.C.S., L.R.C.P.Lond., has been appointed Registrar and Chloroformist to the Evelina Hospital for Sick Children, Southwark-bridge-road, S.E., vice G. A. Carpenter, resigned.

KERR, DANIEL O., M.B., C.M.Ed., has been appointed Medical Officer for the Keelby District of the Caistor Union.

KNAGGS, FRANCIS H., M.R.C.S., L.R.C.P., has been appointed Surgeon to the Gloucester General Infirmary and Gloucestershire Eye Institution, vice Anthony J. Bathe, M.R.C.S., L.R.C.P., L.S.A., resigned.

NEECH, JAS. THOMAS, L.R.C.P.Ed., L.F.P.S.Glas., L.M., has been appointed Surgeon to the Oswestry Dispensary.

POWER, D'ARCY, M.A., M.B.Oxon., F.R.C.S. Eng., has been elected Assistant Surgeon to the Victoria Hospital for Children, Queen's-road, Chelsea.

THOMAS, FREDERICK, M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer for the Upper Ystradyfodwg District of the Pontypridd Union.

THOMAS, G. H. WARREN, L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer and Public Vaccinator to the Teignmouth District, Newton Abbot Union, vice Robert Gibbs, M.R.C.S., L.S.A., resigned.

TURNER, ALFRED, M.B., C.M.Ed., has been appointed Assistant Medical Officer to the Dorset County Asylum.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

BIGGLESWADE UNION, Bedford.—District Medical Officer. Salary £120, with extra medical fees, as allowed by the Local Government Board.—Medical Officer for the Union Workhouse and Infirmary. Salary £40 a year.—Medical Officer for the Contagious Diseases Hospital. Salary £10 a year.

BIRMINGHAM GENERAL HOSPITAL.—Assistant House-Surgeon. Residence, board, and washing will be provided, but no salary.

CLINICAL HOSPITAL FOR WOMEN AND CHILDREN, Park-place, Manchester.—House-Surgeon. Salary £80 per annum, with apartments and board.

DURHAM COUNTY HOSPITAL.—House-Surgeon. Salary £100 a year, with board and lodging.

HOSPITAL FOR WOMEN, Soho-square, W.—House-Physician. Salary £75 per annum, with board &c.

LIVERPOOL DISPENSARIES.—Assistant Surgeon. Salary £80 per annum, with apartments, board, and attendance.

LIVERPOOL ROYAL SOUTHERN HOSPITAL.—Ambulance Surgeon. Board, lodging, and washing provided, but no salary.

MANCHESTER HOSPITAL FOR CONSUMPTION AND DISEASES OF THE THROAT.—Honorary Assistant Physician.

MIDHURST UNION, Sussex.—Two Medical Officers. Salaries £65 and £45 per annum, with extra medical and vaccination fees.

PADDINGTON PROVIDENT DISPENSARY, near Edgware-road, W.—Medical Officer. Usual gratuity £50 a year.

PRISON COMMISSIONERS FOR SCOTLAND.—Resident Surgeon. Salary £200, with an increment of £50 after five years, and a further increment of £50 after ten years, to a maximum of £300, with residence, or allowance in lieu, and medicines.

QUEEN'S HOSPITAL, Birmingham.—Honorary Surgeon.

ST. PANCRAS AND NORTHERN DISPENSARY, Euston-road.—Resident Medical Officer. Salary £105, with residence.—Honorary Physician.

TOWNSHIP OF TOXTETH-PARK, Liverpool.—Assistant Medical Officer for the Workhouse and Infirmary. Salary £100 per annum, with rations of a first-class officer and separate apartments.

UNIVERSITY COLLEGE, London.—Professor of Medicine.

Births, Marriages, and Deaths.

BIRTHS.

BARTON.—On the 1st inst., at Searle Lodge, Market Rasen, the wife of B. Barton, M.D., of a son.

MORTON.—On the 1st inst., at Wellesley-villas, Croydon, the wife of Shadforth Morton, M.D., of a son.

PIGGOTT.—On the 6th inst., at Teignmouth, South Devon, the wife of F. Cecil H. Piggott, B.A., M.B., B.C. Cantab., M.R.C.S., L.S.A., of a daughter.

RAW.—On the 28th ult., at Rutland House, Oakfield-road, Anerley, S.E., the wife of William E. St. M. Raw, L.R.C.P., M.R.C.S., L.S.A., of a daughter.

MARRIAGES.

ALLWRIGHT—LUNNON.—On the 1st inst., at St. Nicholas', Hedsor, Bucks, Frederick William Allwright, M.D., to Dorothy Mary (Dora), only daughter of the late Thomas Lunnon, Esq., of Bourne Bank, Bourne end, Bucks.

GRIMSDALE—JEVONS.—On the 2nd inst., at the Ancient Chapel of Toxteth-park, Liverpool, Thomas B. Grimsdale, M.B., to Helen, daughter of Henry Jevons, J.P., of Liverpool.

HOLT—COOPER.—On the 4th inst., at St. James's, Clapham, H. Lyttleton Holt, M.R.C.S., L.R.C.P.Ed., to Caroline Emily Cooper, elder daughter of William Cooper, of Clapham.

MOIR—BONAMY.—On the 8th inst., at St. John's the Evangelist, W.C., Byres Moir, M.B., to Evelyn, daughter of the late Lieut.-Col. J. Collings Bonamy, of Guernsey.

TOLLER—MACKAY.—On the 1st inst., at Langton-by-Wragby, Lincolnshire, Charles William Edward Toller, M.R.C.S., L.R.C.P., to Florence Heaton, second daughter of the Rev. Sweeu MacDonald Mackay, M.A., Vicar of Langton.

WILES—MCGACHEN.—On the 1st inst., at St. Martin's Church, Fanny Stratford, Bucks, by the Rev. A. H. MacGachen, brother of the bride, assisted by the Rev. A. H. Barrow, Vicar of the Parish, Frederick William, youngest son of the late William Wiles, of Wotton-under-Edge, Gloucestershire, to Sophia Euphemia Auld, younger daughter of the late Rev. J. D. McGachen, Vicar of St. Bartholomew's, Bethnal-green.

WRIGHT—GWYNN.—On the 1st inst., at Emmanuel Church, Clifton, John Frederick Wright, M.R.C.S., to Ethel Gwendoline, third daughter of the late John Crowther Gwynn, of Clifton, Solicitor.

DEATH.

OLIVER.—On the 7th inst., Samuel Oliver, M.R.C.S., L.R.C.P.Ed., of Buckingham Palace-road, and Enfield, Paignton, South Devon, in his 53rd year.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

PHYSICIANS IN ANCIENT ROME.

R. C. L. (Newcastle-on-Tyne).—The status of the profession in Ancient Rome was first recognised by Caius Julius Cæsar when he came to wield absolute power. "Omnes medicinam Romæ professos," says Suetonius, "et liberalium artium doctores, quo libentius et ipsi urbem incolerent et ceteri adpeterent, civitate donavit. (He vouchsafed the right of citizenship to all who in Rome professed the healing art, and who gave lessons in liberal education, in order that they themselves might the more willingly settle in the City, and that others similarly qualified might repair to it.)

Dr. L. Marshall.—We fear the communication is too lengthy for publication.

Mr. Kendrick.—The specimen is under examination.

"SWEATING OF THE FEET."

To the Editors of THE LANCET.

SIRS,—To cure the moisture of the feet every effort should be made to secure rapid evaporation. From personal experience this end, I find, can best be obtained by the use of sanitary clothing, porous throughout and made exclusively of animal material, which is a non-conductor of heat or electricity. So far as the feet are concerned, the sock or stocking is made of pure animal wool, free from all dyes or colouring material. The separate division given for each toe, as for a glove, keeps the foot cool by preventing the accumulation of sweat. We should soon suffer with our hands if gloves were made of one piece, holding the fingers tightly together, as the toes in a boot. The true sanitary boot should be made of woollen cloth or very porous leather with cloth uppers. It is lined with pure woollen lining. There is a hole in the upper part of the heel, and the inner soles or layers of leather are perforated. Each step is supposed to pump air in and out of the boot. However this may be, the fact in any case remains that the foot is kept at once warm and yet cool. There is no sense of stuffiness or closeness. The foot does not swell. Whatever moisture arises at once evaporates. The foot therefore remains dry and warm, but is never over-heated and offensive. The bad odours that vegetable lining and socks—cotton socks, to wit—retain are thrown off by nature's clothing—i.e., animal wool. This is a fact I have particularly noticed when travelling in hot countries. My cotton socks soon became obnoxious, even when constantly changed, though my feet were in a healthy state; but now that I wear sanitary boots I never suffer any inconvenience. My woollen socks keep my feet pleasantly cool and dry and free from all odour. But it is no use wearing woollen socks with a boot that has cotton or linen lining. The foot must be covered throughout with porous animal material.

I am, Sirs, yours faithfully,

June, 1887. ADOLPHE SMITH.

"WINTER PALACES OF HEALTH AT HOME."

REFERRING to Dr. B. W. Richardson's suggestion, as noticed in our issue of May 28th, *Mr. Richmond Leigh* writes:—"In the Crystal Palace we have a spacious winter-garden, in which suites of rooms for invalids and delicate-chested individuals could be put up at a reasonable outlay and let at a fairly moderate charge. The Palace also possesses the great advantage of a large and varied selection of amusements, besides schools of art, &c., to occupy the minds of the residents and prevent *ennui*. It is conveniently near to London, whence, it may be presumed, it would draw its largest contingent of patrons, and would also allow friends residing in the metropolis to visit the invalids frequently. The locality is of little import under glass. The contained vegetation, another advantage already in action at the Palace, would preserve the purity of the air, and little ventilation would be required, while dampness need not be apprehended. The luxuriant growth of the bananas and palms in the Crystal Palace is the test of its climate, and the proof of its suitability to phthisical and other invalids."

M.B.—1. If A entirely ignores the work of his Poor-law appointment, he is decidedly infringing the regulations of the Local Government Board; and in regard to his vaccination appointment the same rule holds good with greater force.—2. We should recommend "M.B." to live within his district, and leave others to report to the Central Board his opponent's non-compliance with their regulations.

Boston.—The Morton lectures will be delivered by Sir James Paget at the Royal College of Surgeons of England. The date has yet to be announced.

M.R.C.S.—Scarification with a very cold scalpel, the skin being frozen, has been successful (see THE LANCET, March 23rd, 1878, p. 421).

THE NEW MEDICAL ACT AND STUDENTS.

To the Editors of THE LANCET.

SIRS,—I should be very grateful if you would insert this letter in your next issue, as, if the Councils of the Colleges of Surgeons and Physicians would make the concession I plead for, many students would benefit by it. The student who registered on Oct. 1st, 1883, is seriously affected by the New Medical Act, as he began his studies thinking that he could take either the diploma of M.R.C.S. or L.R.C.P.L., and register it alone; and being thirteen days short of forty-five months he is unable to present himself at forthcoming examinations, kindly held by both Colleges in order that many of those who entered, thinking they were entitled to register and practise with either one degree, may have an opportunity of presenting themselves with a view to doing so. As he is now obliged to take both, I would plead that he may be allowed to present himself for examination at whichever College he was preparing for two years after passing first subject of primary, instead of two years from completing it, and for the following reasons:—First, if a student passed in anatomy, and was referred for six months in physiology, no one would, I think, suggest that he could read that subject alone during the whole period; and what he really does is to attend various out-patient departments and the post-mortem room, and read up the referred subject in early morning and evening. Secondly, it is not usual for a student to present himself at both Colleges for the finals held in the same month, so that two years would have been spent probably in hospital practice, from the time of completing the primary, before he had obtained both diplomas; and even if that were made a condition, it would be a great boon to many students. At the time of passing the first part of the primary he would then make up his mind which he intended to go in for first, and give greater attention to it for two years from then, afterwards spending the remainder of the time from the passing of the last part of the primary till two years had expired, preparing for examination in the remaining subject or subjects.

I am, Sirs, yours obediently,

May 31st, 1887. A STUDENT.

Mr. W. Longbottom.—Dr. Kollscher has not, we believe, completed his investigations on the subject. We shall probably be in a position to publish further particulars shortly.

Mr. G. W. E. Russell will see, by reference to an annotation in another column, that the subject of our correspondent's letter is engaging attention.

INCISING THE TONSILS.

To the Editors of THE LANCET.

SIRS,—I attended lately a woman who was suffering from tonsilitis, there being even more than the usual tumefaction. Upon visiting her one day in the course of the disease I was anxious to incise the tonsil at once, and not having a bistoury with me at the time I did so with an ordinary blunt-pointed dressing scissors, and with the best results. It struck me upon thinking over the matter afterwards that perhaps it would be better to use a blunt-pointed scissors in every similar case. The danger of wounding an artery is altogether obviated, there is no difficulty whatever in getting a good grip with the scissors upon the swollen tonsil, and the preliminary preparation of a bistoury with lint, which is wrapped round it, is avoided. I admit that there is very little danger of wounding an artery with a bistoury used in the customary way; still it is better to have no danger at all than a little.—Yours respectfully,

Deptford, S.E., May 26th, 1887. R. B. GOSNOLD.

LANGMORE DEFENCE FUND.

A SUM a little more than £70 is still required to defray the heavy bill of costs for legal defence incurred by Dr. J. Wreford Langmore in the recent groundless action brought against him in consequence of his having signed a lunacy certificate, in compliance with a magistrate's order. The committee desire to close the fund, and will thank all gentlemen wishing to subscribe to send their donations at once to Mr. George Eastes, M.B., 69, Connaught-street, Hyde Park-square, London, W., the honorary secretary to the fund. The donations already acknowledged amount to £151 4s. Those received during the last three weeks are the following:—

"A Friend in the Fells"	£2	2	0	Mr. R. J. Godlee	...	...	£1	1	0
Proprietors of THE LANCET	2	2	0	Mr. T. A. Rogers	...	...	1	1	0
Mr. John Morgan ...	2	2	0	Dr. John Williams	..	...	1	1	0
Dr. J. Russell Reynolds ...	2	2	0	Mr. H. P. Young	...	...	0	10	6
Dr. J. F. P. Staples ...	2	2	0	Dr. Maurice Davis	...	...	0	10	0
Dr. A. B. Garrod ...	1	1	0	Dr. J. C. Thorowgood	...		0	5	0

"TREATMENT OF TÆNIA SOLIUM."

To the Editors of THE LANCET.

SIRS,—Being an old resident in South Africa, I can fully confirm the assertion of your correspondent, Dr. Fred. A. A. Smith, as to the frequency of worms among the natives—so much so that you will seldom see a Kaffir's necklace without some pieces of root among the charms, some probably of the male fern, as they know of that remedy. I have a piece of root still in my possession which was given to me by a Kaffir man, and of which I wrote at the time from his dictation: "The root umfissé, or umfézé. The flower they call 'cenjiganjyambo.' A most valuable medicine. The plant (I understand) attains no more than six inches in height." To this is appended the man's directions for use in the case of worms. Does Dr. Smith know the colonial remedy for worms often used among the Boers—the inner bark of the root of the pomegranate? The rind of the fruit is used by them in dysentery.

I am, Sirs, yours faithfully,

Doughty-street, W.C., June, 1887. M. CAREY-HOBSON.

FOUNDLINGS IN ITALY.

DR. B. RASERI, of the Italian Bureau of Statistics, has recently issued a valuable report on the subject of illegitimate births and foundlings in Italy. Of 187,555 illegitimate children born in the 8260 communes of the kingdom of Italy during the three years 1879, 1880, and 1881, 122,782 were recognised by one or both of their parents, while the remainder, 64,773, were brought to the civil offices, each by a stranger (midwife, accoucheur, &c.), with the declaration that the mother did not wish to declare the proper name of the child. In the years in question (1879-81) the infants found exposed were 40,296 alive, and 600 dead. Of these 32,093 were found in the turning boxes intended for their reception, 541 of them dead, and 8823 were found on the public roads, under staircases, in churches, &c., 79 of these being dead when found. Out of a total of 227,851 illegitimate children and foundlings in all Italy during the three years 1879-81 public charity took charge of only 106,461, the greater number recognised by their parents, having been provided for by them, or having died before the communes concerned had time to take measures in their behalf.

Scot.—Is our correspondent quite sure of the accuracy of his diagnosis? Iodide of potassium might be tried.

THE L.S.A. AS A DOUBLE QUALIFICATION.

To the Editors of THE LANCET.

SIRS,—According to the decision of the General Medical Council the licence of the Apothecaries' Society, London, will be a licence to practise surgery, as well as medicine; after July 1st, 1887. Should not those men who have already passed the examination in surgery (conducted by the same examiners—Messrs. Makins, Walsham, and Andrew Clark—as were recently appointed by the General Medical Council) be also recognised by the General Medical Council as possessing a licence to practise surgery? I am, Sirs, your obedient servant,

June, 1887. L.R.C.P.

*** The question asked by our correspondent is a very reasonable one. Unfortunately, law and reason do not always coincide, and there may be a difficulty in the Society acting on any examination retrospectively. We commend the letter, however, to the consideration of the Society.—ED. L.

Enquirens should refer to a letter which appeared in our issue of Dec. 6th, 1884, p. 1030.

TO PASTURES NEW.

To the Editors of THE LANCET.

SIRS,—I am a physician, &c., with indifferent health and a small private income (about £120 a year). I am anxious to emigrate, but do not know where to go. Perhaps some of your readers would kindly give me some hints on the subject. I am a bachelor, and fond of country life and sport. Any good climate, with a chance of £260 a year, would suit me; and for information I should be very grateful.

I am, Sirs, yours faithfully,

June 4th, 1887. EMIGRANS.

MUSHROOMS: THEIR NUTRITIVE VALUE.

THE Vienna school has been investigating this subject, and has arrived at conclusions of importance for all countries where, like Austria, the edible fungi are a common food. The traditional view has been that mushrooms are equal in nutritive value to butcher's meat, and physiologists, like Lorinser in his work on "The More Important Fungi" (Vienna, 1883), have urged, in the interests of the poor, the more frequent use of an aliment so easily procurable and so sustaining. Dr. Stromer of Vienna has, however, after repeated and carefully checked investigations, reached the following results:—1. The fresh mushroom differs widely from the dry mushroom, the former containing 90 per cent. of water and only from 2 to 3 per cent. of albumen, while the latter contains 28 per cent. of albumen. Moreover, the different parts of the mushroom contain more or less albumen, the "hat," for instance, having twice as much as the stem. 2. The fresh mushroom contains 2·5 per cent. of carbon hydrates, while the dry contains 24·5 per cent. of them. Experiments conducted on Stutzer's method give the following results as to the digestibility of mushrooms:—Out of 4·7 per cent. albumen in the *boletus edulis* there was digested 79 per cent., of 5·6 per cent. albumen contained in the "hat" there was digested 80 per cent., while of 2·7 per cent. albumen contained in the stem there was digested 75 per cent. Compared with other aliments this means difficult digestion. Black Vienna bread contains 1·2 per cent. albumen, and of this, in the same time, 86 per cent. was digested; bean-meal contains 3·6 per cent. albumen, and of this, also in the same time, 91 per cent. was digested; pease-meal, with 3·9 per cent. albumen yielded 95·6 per cent. to digestion, raw ham 98 per cent., and grated butcher's meat as much as 99·25 per cent. Results, the same to a fraction, were reached by Saltel of Amsterdam and Mörner of Upsal. Dr. Stromer concludes: 1. Mushrooms possess small nutritive value, their heavy charge of water reducing to very little their quantity of nutrient substances, and, above all, the albumen, which is difficult of digestion. 2. Dry mushrooms are not much better, because they absorb a great deal of water in cooking. 3. Mushrooms approximate in nutritive value to vegetables, particularly to cabbage, and, being cheap and easily procurable, deserve *pro tanto* the attention of the poor.

Mr. J. Peters.—As far as we can make out, the case is still *sub judice*; we therefore refrain from comment.

"SPECIALISM IN EXCELSIS."

To the Editors of THE LANCET.

SIRS,—In reference to your amusing paragraph with the above heading in a recent issue of THE LANCET, it may interest some of your readers to hear that the ancient Egyptians, although they may not have had an "Association of Genito-urinary Surgeons," appeared to have practised specialism *in excelsis*. For we learn, on the authority of Herodotus, that each single disease had its special physician (De Bello Persico, 2, 84). They, however, seemed to have drawn the line at the belly, which, with its contents and all below it, was given in charge of one man. I am, Sirs, yours obediently,

Brighton, June 5th, 1887. W. A. H.

THE VIENNA INTERNATIONAL CONGRESS OF HYGIENE.

G. A. P. (Birmingham).—In July next the working committee of this great gathering will be in a position to issue to all members a detailed programme, including the topics entered for discussion. It is still receiving numerous announcements of intending participants in its business, not merely from medical men, but from members of other more or less cognate professions. The programme will be found to include every subject bearing directly or indirectly on public health. The Dutch, the Swiss, and the Saxon Governments have each nominated their representatives. The exhibition of hygienic appliances will be unprecedentedly rich, thanks to the contributions already received or promised from the various European and Transatlantic States. All members of the Congress will be presented with a "Hygienic Guide to Vienna," having a plan of the city annexed, and indicating every object of sanitary interest within its gates. The Austrian railways are in treaty with the French and Belgian lines, as well as with the Triester-Lloyd and the Danube Steam Navigation Company, to reduce their fares by 50 per cent. for all members of the Congress.

J. W. Black, F.R.C.S.—The subject is one of some delicacy; but we feel very strongly with our correspondent.

THE BROWN DEFENCE FUND.

To the Editors of THE LANCET.

SIRS,—Kindly insert the following:—Amount already acknowledged, £20 9s. 6d.; the Proprietors of THE LANCET, £2 2s.; A Fellow Sufferer, £1 1s.; small sums, 9s.

I remain, Sirs, yours faithfully,

G. STANLEY MURRAY, M.D.A.

28, Upper Richmond-road, Putney, June 7th, 1887.

Medical Diary for the ensuing Week.

Monday, June 13.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M; Thursday, 2.30.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesday, 2.30 P.M.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—4 P.M. Prof. Christopher Heath: Certain Diseases of the Jaws—Diseases of the Temporo-Maxillary Articulation and Closure of the Jaws.

Tuesday, June 14.

GUY'S HOSPITAL.—Operations, 1.30 P.M. and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 1.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Mr. J. D. Malcolm: The Condition and Management of the Intestine, after Abdominal Section, considered in the light of Physiological Facts.—Dr. Radcliffe Crocker: Dermatitis Gangrenosa Infantum.—Mr. Hutchinson: On a form of Chronic Inflammation of the Lips and Mouth which sometimes ends fatally and is usually attended by some disease of the Skin.

Wednesday, June 15.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesday and Thursday, 1.30 P.M. Surgical Consultations, Thursday, 1.30 P.M.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.

LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.

KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; Friday, 2 P.M.; Saturday, 1 P.M.

CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9 A.M.; Saturday, same hour.

Thursday, June 16.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Ophthalmic Operations, Friday, 1.30 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

Friday, June 17.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

Saturday, June 18.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

SUBSCRIPTION.

Clinical Lecture
ON
FUNCTIONAL DISEASES OF THE LIVER.

By SAMUEL FENWICK, M.D., F.R.C.P.,
PHYSICIAN TO THE LONDON HOSPITAL.

(*Continued from page 1175.*)

In what way can we explain the sudden change from an excess to a deficiency of the salivary salt that we have seen occur, not only in phthisis and cancer, but also in many cases of long-standing inflammations? I think the most probable hypothesis is that the nutritive organs are at first stimulated to unusual activity in order to supply the materials for increased growth, and that we then find the sulphocyanide in excess; but that this augmented functional activity is after a time succeeded by a corresponding depression, in accordance with the law that an excessive exercise of any organ is followed by a diminution of its functional power, and that when this occurs the patient exhibits the proof of it in his loss of strength, flesh, and colour, as well as in the deficiency of the salivary salt. We have before seen that an increased growth of structure, whether local or general, must be accompanied by a sufficient power of digestion, in order that the sulphocyanide should present itself in increased amount; it will be therefore necessary to inquire into the state of the salivary salt in various diseases of the digestive apparatus when there is no demand made upon them for unusual exertion.

In the earlier stages of stricture of the œsophagus and of the pylorus the amount of the salivary salt is generally either normal or above the usual quantity, so long as sufficient food can be taken to maintain the nutrition of the body; but as soon as this ceases to be the case the quantity sinks below the normal. In cancer of the stomach, as I have before mentioned, the amount generally soon becomes subnormal. In gastric catarrh it is usually above the normal, probably because this condition is so often associated with acute congestion of the liver. In atonic dyspepsia, on the contrary, the amount is ordinarily subnormal; in fact, this is by far the most frequent cause of a deficiency of the sulphocyanide, for 39 out of 111 "private cases," in which the amount was below the average, were instances of this disorder. They were all very severe cases, the appetite being bad in all; in many the sensation of hunger was totally absent, or was replaced by a loathing of all food. It is probable that feebleness of the stomach is a common cause of a deficiency of sulphocyanide in various chronic maladies, for in 84 persons presenting this condition the appetite was stated to be bad in 55, moderate in 12, and good in only 17 of the whole number.

Vomiting is a common accompaniment of a deficient amount of the sulphocyanide, but this has only been observed where the rejection of the contents of the stomach was frequent and complete. It is not the case in the so-called "hysterical vomiting," and the condition of the saliva might possibly be of value in the diagnosis of this latter condition. In phthisis vomiting assists in enfeebling the patient, and also in producing the small amount of the salivary salt we have before seen is common in the latter stages of that disorder. But it is only fair to remind you that in vomiting there is generally an increased flow of saliva, and we may doubt whether the deficiency of the sulphocyanide may not be due, in certain cases, as in gastric cancer, to exhaustion of the salivary glands, arising from their undue action. This objection is, however, disposed of by the fact that in some of the cases of gastric cancer where the vomiting was relieved by the regular washing out of the organ, there was no increase thereby produced in the quantity of the salivary salt.

An occasional attack of diarrhœa or the exhibition of a purgative does not seem to affect the quantity of the sulphocyanide; but if dysentery or diarrhœa has been continued long enough to diminish the general nutrition, it then falls below the normal amount. Thus 23 per cent. of the cases observed in the "private cases," who presented a decrease of the salivary salt were suffering from one or other of these conditions. It is of course possible, if the saliva be examined only after the cessation of the dysentery, that you may find an excess instead of a deficiency of the sulphocyanide, as an unusual demand may be made on the digestive organs in order to repair the loss occasioned by the undue waste. Thus, a patient was admitted on Oct. 27th, 1883, with a sharp attack of dysentery which had commenced on that day; the discharge of blood and mucus entirely ceased on the 31st, and the saliva then was +4. It remained at the same point two weeks longer, when it fell to +2½, and finally in the sixth week to +1, when he was discharged cured.

From a consideration of the effects of long-standing diarrhœa, we might have conjectured that any cause that prevented the absorption of the digested food from the intestine would be followed by a change in the saliva. I had not, however, thought of this. I was therefore much surprised to discover a marked alteration produced by the tapping of persons suffering from ascites arising from cirrhosis. The saliva of a man affected with this complaint, whose abdomen was tensely distended with fluid, was examined on May 11th, and found to be −3°; on the 14th he was tapped, and three days afterwards the sulphocyanide had risen to +2½; on the 28th it had again fallen to −1°, but on that day 470 ounces of fluid were removed by aspiration; and on the 31st it had risen to +2½, after which date it gradually declined each week to +2, +1½, +N, subsequently to which there are no records. In a second case the sulphocyanide was only −3 on November 15th; on the 20th tapping was performed, and on the same day it rose to +½; on December 28th it was only −1°, when aspiration was again practised, but the patient sank a few days afterwards. Three cases of this kind are recorded, each being tapped twice; the average quantity of the sulphocyanide was −1·8 just before the operations, and +1·04 shortly after them. This is not due simply to the removal of an obstruction from the general circulation; for no alteration in the amount of the salivary salt was observed after aspiration of the pleura, nor did it occur where the distension was only moderate, as you will see in a man suffering from ascites dependent on cirrhosis at present in the wards. In this latter case the fluid had been collecting for three years, and although there was a considerable quantity of liquid in the peritoneum, there was no great amount of internal pressure. He was tapped at his own request, and the saliva was not below the normal point before the performance of the operation. On the other hand, the sulphocyanide may be below the normal in ascites arising from other causes, not from the pressure of the fluid, but from imperfect digestion, and in this case the tapping does not alter the amount. For example, a man suffering from cancerous tumours of the abdomen was admitted, whose peritoneum also contained a considerable quantity of fluid. On Nov. 14th the saliva was normal; tapping was employed the same day in the hope of relieving his pain, and on Nov. 21st the quantity of sulphocyanide was −½; on Nov. 28th it was −½, and he was aspirated on Dec. 1st; on Dec. 6th it had sunk to −3°, and he died from exhaustion on Dec. 8th. I think, then, we may conclude that when the amount of the salivary salt falls much below the normal in persons suffering from ascites arising from cirrhosis, tapping is indicated; and that where there is a rapid increase in the sulphocyanide after the operation, it is probable that the former condition had resulted from pressure on the portal vessels, and not from causes immediately impairing the digestive organs.

On commencing these inquiries I suspected that the presence of the sulphocyanide in the saliva would be found to depend on a decomposition of the biliary salts, and that an increased amount would be observed in all cases of jaundice. On the contrary, in one instance of jaundice arising from duodenal catarrh in the "later hospital cases" the salt was −2 in the first week of the illness; in the next, in which the yellowness of the skin was much diminished and the colour of the stools improved, it rose to −1°; and in the third, when the patient was dismissed, it amounted to +2°. In a second case it was −2° on admission; three days afterwards it was normal; on the tenth day, when the patient had greatly improved, it was +1°; and he was dismissed cured on the nineteenth day. Taking the "earlier hospital cases," where the variations of the sulphocyanide were less minutely recorded, I find that of twenty-three

Digitized by Google

affected with jaundice the salivary salt was deficient in eighteen, and in some of them not a trace of colour could be obtained by the addition of the perchloride of iron. In two the quantity was normal, but one of these had so far recovered as to have been placed on full diet, and in the other post-mortem examination proved the jaundice to have resulted from the rupture of a hydatid cyst into the ducts of the liver, the opening of the common duct being only partially obstructed, and bile being present in the duodenum. In three cases the quantity was above the normal, and in one of these there was cancer of the liver; the histories of the others could not be obtained. From these observations it would seem probable that in order that the salt should appear in the saliva the bile must be able to enter the duodenum, and this seems to be supported by the fact that in two cases admitted into the hospital, where large quantities of bile were expectorated, probably from perforation of the lungs by hydatid cysts of the liver, scarcely any colour could be produced in the saliva by the addition of the solution of iron. Supporting the same conclusion is the circumstance that in some cases of jaundice the depth of the colour varies always with the amount of the salivary salt. Thus a lady had suffered for three weeks from jaundice arising apparently from hypertrophic cirrhosis; the skin and urine were deeply tinged, the stools white, and the saliva free from sulphocyanide. She was treated by perchloride of mercury, and in three weeks the stools became partially coloured, and a slight tinge was produced in her saliva by the addition of iron. In two weeks afterwards diarrhœa occurred, the stools being deeply stained with bile, and although the skin and urine remained yellow the saliva contained an abundance of the salt. Again, a gentleman had been for three months deeply jaundiced, the saliva being −2°. In two months afterwards the jaundice had greatly lessened, the stools were brown coloured, and the saliva was +2. Two or three weeks afterwards he had a severe attack of pain in the abdomen, with an increase of jaundice, and the sulphocyanide again became deficient. When I last saw him he was much better, and the salivary salt was again +2°. In *severe* cases of jaundice the deficiency of the sulphocyanide is, unless cancer be present, greatest at the commencement of the case, for I found in the "earlier hospital cases" there was, on the average, twice the quantity in the saliva of those examined five weeks after the onset of the disease that there was in those who came under observation in the first week of their illness. This rule, however, does not hold good for the temporary cases following severe pain of the abdomen, and usually referred to the passage of gall-stones. In two instances of this kind the saliva was normal, even at the commencement, and the jaundice passed away in a few days. Although there are other circumstances that modify the conclusions that seem necessarily to arise from the above facts, we may lay it down as a general rule that a deficiency of the salivary salt in the first week of jaundice is unimportant, but that when it persists after many weeks' duration it is of evil omen, as pointing either to an insuperable stricture of the common duct or to some malignant growth that is sapping the strength of the patient.

In every case of lead colic the sulphocyanide was absent, or present in diminished quantity, until the urgent symptoms subsided, after which an excess was usually observed. Let me quote to you one or two instances from the "later hospital cases." A man, aged twenty-four, was admitted into the wards with lead colic of six days' standing on July 13th, and his saliva was noted as −2°. The bowels were freely moved by medicine, the pain and vomiting were relieved, and on the 17th it was +1°. A man, aged thirty-six, was admitted with lead colic of two days' duration on July 16th; on July 19th the pain of the abdomen was less and the bowels had acted, but he complained of pain in the epigastrium, and the saliva was −1°; on July 26th he had no abdominal pain, and the saliva had risen to +1½; on Aug. 2nd he was still free from pain, and the saliva was +2°. A man was admitted on Oct. 1st with lead colic; on Oct. 4th the saliva was −½, and on Oct. 11th, when the pain had quite left him, it had risen to +2. The cause of this diminution in lead colic is, however, susceptible of explanation on the supposition that, as the saliva was always very thick and tenacious, the lead might have acted directly as an astringent upon the salivary glands. I therefore stimulated the secretion by the application of tincture of pyrethrum to the tongue, but, although the quantity of the fluid was increased, there still remained a deficiency of colour on the addition of perchloride of iron. I therefore came to the conclusion that the alteration in the amount of the sulphocyanide was not due to a mere local cause. But however we may explain the diminution of the salivary salt in lead colic, the fact may be of great use in diagnosis. We see occasionally symptoms of peritonitis, of gastric ulcer, and other abdominal disorders in persons who have a blue line around their teeth, and in such instances it is difficult to determine whether the symptoms are due to the absorption of lead or not. The state of the saliva may settle the point, and thus indicate the treatment that should be undertaken for the patient's relief.

In all cases where the symptoms and physical signs have pointed to acute congestion of the liver arising from the abuse of alcohol, overfeeding, or indolence, I have remarked the amount of the salivary salt to be above the normal amount. In chronic congestion of any organ, as we see exemplified in congested kidney resulting from disease of the heart, its functional activity is lessened, and it is not able to resume its normal powers of secretion until the pressure is removed. Let us, then, ascertain the state of the saliva in heart disease, and see if any similar change occurs.

In cases of aortic regurgitation, as you are aware, pressure upon the general venous system only occasionally takes place, so that we should not expect to find much alteration in the saliva. In six cases of this kind the average amount of sulphocyanide was only +·43, and the following table shows that there was very little change when they were examined each week during the period of their residence in the hospital.

TABLE IV.—*Showing the state of the Saliva each week in Cases of Aortic Regurgitation.*

	Number of weeks in hospital.				
	1	2	3	4	5
Average amount of sulphocyanide ...	+·50	+·12	+1·25	+·66	+1·2
Number of cases examined	2	4	1	2	2

Now, although in the above figures you will observe the amount is greater in the fifth than in the first week after admission, there is no evidence of a regular increase; for in the second week it is smaller than in the first, and in the fourth it is very little above what was remarked in the first. We may conclude, then, that if the quantity of the salivary salt is an index to the activity of the digestive powers, these suffer but little in regurgitation through the aortic orifice.

Now let us examine cases of dilatation of the heart and of mitral disease in which pressure upon the venous system is sooner or later developed. Here the difference is most striking, as there were eight cases in which either the patients died or were removed by their friends in a dying condition, and of these five presented on their admission to the hospital an average of −·95. In two cases it was on admission above the normal amount, but in each, as time went on, there was a gradual decrease in the salivary salt. Thus in one it was at first +2½, next week +1½, after which no further examination is recorded; in another it was at first +2¾, then it fell successively to +2 and +½, which was quickly followed by death. On the contrary, wherever there was a steady improvement there was a weekly augmentation in the quantity of the sulphocyanide. To illustrate this I have added the following table.

TABLE V.—*Showing the Weekly Amount of Sulphocyanide in the Cases of Mitral Disease that improved in the Hospital.*

	Weeks in hospital.						
	1	2	3	4	5	6	7
Average of Sulphocyanide	+·47	+1·1	+·66	+1·7	+2·2	+2·9	+2·5
Number of cases examined	12	12	12	10	5	5	1

If you look at this table, you will remark that, although there is a decrease in the third as compared with the second week, the rise week by week in all the periods was gradual, marking, we may suppose, the diminution in the pressure on the venous system, and thus allowing the digestive organs to regain their normal condition. But you will naturally ask, How it is that heart cases during convalescence

Digitized by Google

should show such an increase of the salivary salt? It is, I suspect, because during the illness the general nutrition has suffered, and the system calls, as after typhoid, for an augmented quantity of new material, and consequently the digestive apparatus is stimulated to unusual activity. But in heart disease we should remember that the respiratory functions are as much or more disturbed than the digestive. May not the variations in the saliva, then, be due to the pulmonary congestion, and not to that of the liver? I think this is not the case, because in the later stages of phthisis we found the salivary salt was always much below the normal point, although difficulty of breathing is a marked feature in that stage of the disease. But, however we may explain these facts, there is no doubt, if their accuracy should be confirmed by future researches, that the condition of the saliva places in our hands a valuable aid in the prognosis and treatment of diseases of the heart. When there is a gradual increase in the amount of the sulphocyanide, we may hope that the pressure on the venous system is diminishing and the digestive organs are regaining their functions; whilst when the quantity sinks week by week, we can only look forward to a decay of the vital functions and to a fatal termination of the case. I have only examined one case of acute yellow atrophy of the liver. A woman was admitted with jaundice of two or three weeks' duration, and there were no symptoms indicative of this fatal disorder. On examination of the saliva, the ordinary colour produced by the addition of the perchloride of iron was absent, but it had a brownish tinge, and I remarked to the students present that in all probability, although the case was an obscure one, it would prove dangerous or tedious. Delirium set in suddenly, the space of the hepatic dulness rapidly diminished, and she died in two or three days. I have been informed by Mr. Hurry Fenwick that he has remarked a brown colour in the saliva on addition of iron in cases of pyæmia, but I have not myself verified the observation. It is, however, worth while to bear this in mind as various modifications of the sulphocyanide may perhaps be discovered in different diseases. If we should find that the ordinary salivary salt is always absent in cases of acute yellow atrophy of the liver, it may enable us to suspect the presence of this formidable malady where there are no other indications of it. I have found that the quantity of the salivary salt occasionally differs to a considerable extent from the normal in those who seem to be in good health, and it therefore becomes a matter of interest to inquire whether persons who present this condition are more prone to disease than others, and if so, to what maladies they are especially liable. At an early period of these inquiries I was struck with the unusual quantity of the sulphocyanide secreted by persons suffering from acute rheumatism, and this fact was confirmed by both the gentlemen who so kindly assisted me. Of thirty-six cases of this disease recorded in the "earlier hospital cases," all but one, whose saliva was normal, showed a marked excess of sulphocyanide, the amount varying from eight times to twice the ordinary quantity. As I before explained to you the depth of the colour in the earlier observations was not so carefully estimated as afterwards, so I shall now confine myself to the results obtained by the later and more accurate inquiries. Fifty-five were recorded in the "later hospital cases," which are grouped in the following table according to their stay in the hospital, but these include a considerable number of subacute and gonorrhœal cases, in which the quantity of the salivary salt is usually small, and consequently the average quantities are much less than you might expect from the former statement.

TABLE VI.—*Showing the Amount of Sulphocyanide in Cases of Rheumatic Fever grouped according to their duration in the Hospital.*

	Period of residence in hospital.			
	7 days.	7 to 28 days.	28 to 56 days.	Above 56 days.
Average depth of colour... ...	+·33	+·94	+·1·7	+2·62
Number of cases examined ...	3	26	22	4

You will see by the above figures that there was a gradual rise in the amount of the sulphocyanide in proportion to the length of time required to afford permanent relief to the patients. Those included in the first column were either relapsed or doubtful cases of rheumatic fever, but I thought it was more fair to include everyone who was admitted with the diagnosis of acute rheumatism, even if the correctness of the diagnosis was doubtful. I need not tell you that acute rheumatism does not run a regular course; it consists of a succession of febrile attacks attended with articular inflammations, and you will be able therefore to understand that the smaller the quantity of the salivary salt, the less is the tendency to the recurrence of these attacks.

But the state of the saliva affords also a measure of the severity of the attacks—that is, of the number of joints that are simultaneously affected,—for when many joints are implicated the patients are obliged to apply to the hospital earlier than those in whom only one joint is painful, or where the pain is so slight that they can continue at their employments. In the following table the cases are grouped together according to the length of time the pains had been felt before their admission.

TABLE VII.—*Showing the Cases of Rheumatic Fever grouped according to the duration of the illness before admission into the Hospital.*

	Duration of pains before admission.		
	Under 7 days.	7 to 21 days.	Above 21 days.
Average depth of colour ...	+1·65	+1·31	+1·18
Number of cases examined...	23	24	8

It may, of course, be objected that other causes besides the severity of the attack influence the early application of the patients for hospital treatment, but that this is the chief reason seems to be borne out by the experience of Dr. Hilton Fagge at Guy's Hospital; for he remarks: "A point which comes out clearly from the last column is that a comparatively long duration of the disease after admission is by no means peculiar to patients admitted at a very early period of the illness. On the other hand, it may be noticed that the cases which subsided most rapidly whilst in the hospital had already been running on for three weeks; and I am not sure that this is a mere accident, for on tabulating ten other cases which have since occurred at Guy's, and in which rapid recovery has taken place without treatment (or under treatment which I believe to be ineffectual), I find the average duration of the disease before admission was 13·7 days."[1] But you may say that, as it has been already stated that in all inflammatory disorders there is an increase of the salivary salt from the demand made upon the organs engaged in nutrition, why may not this be the reason of the excess in acute rheumatism? For the simple reason that there is no difference to be remarked during the period when the joints are affected and the intervals when they are free from inflammation; and also because, even when the attacks have subsided, and the patients are able to leave the hospital, the excess of the salivary salt has still been observable. To show this I have constructed a table. (See Table VIII.) You will remark that in each group the depth of colour was nearly the same in the week when the patients were dismissed as when they were admitted, so that, notwithstanding the pains were relieved, the excess of the sulphocyanide remained. It is also worthy of observation that no effect appears to have been produced upon the saliva by the treatment. Nevertheless, after the patients left the hospital the excess of the sulphocyanide seems to have disappeared. Thus, four patients were readmitted on account of return of pains in the limbs; one on his first admission presented a colour of +3½, which fell to +2, and he was readmitted with +1½; another had a colour of +3½, which had fallen to +2½ when discharged, but when readmitted it was only +1½; another on his first admission presented a colour of +2, it was +2½ when he left the hospital, but it was −¾ when readmitted; a fourth returned one month after leaving the wards with a colour of −3. In all of these the pains on readmission were slight, there was scarcely any rise of temperature, and they were quickly again discharged cured. But there is another objection that has probably occurred to your minds. May not the excess of the sulpho-

[1] The Principles and Practice of Medicine. By Dr. Hilton Fagge. Vol. ii., p. 538.

Digitized by Google

cyanide in acute rheumatism and in all the febrile diseases hitherto examined be due to the increased temperature of the body, and be therefore merely an indication of the augmentation of the destructive processes by the fever, or of the inspissation of the saliva accompanying it? Table IX. has been prepared to test the truth of this objection, and was formed by calculating the average evening temperature of each case during its residence in the hospital; the whole of the cases being then grouped according to the temperatures thus obtained.

,, ,, ,, 99° & 100°	42	+1·92
,, ,, ,, 100° & 101°	22	+1·5
,, ,, above 101°	11	+1·43

It will be remarked that the highest quantity of the sulphocyanide was in the cases in which the average temperature was 98° to 99°, and that it lessened as the average amount of heat increased, so that there is no connexion between the quantity of the salivary salt and the increased retrograde processes that are believed to occur in fever. In acute rheumatism the saliva is always abundant, so that there is no reason to suppose the augmentation in the amount of the sulphocyanide is the result of an inspissation of the secretion.

But it may be said, Is not the temperature a measure of the intensity of the disease, and ought not, therefore, the elevation of the thermometer to correspond with an augmentation of the sulphocyanide? But the *average* evening temperature does not represent the severity of the illness, for the highest temperature in each case usually occurs during the first four days after the patient's admission, and in short cases, where there is no recurrence of the fever, the patients are quickly dismissed, and consequently the average temperature is high. But where there is a frequent succession of attacks, attended with a moderate rise of temperature, the patients remain long in the hospital, and the average height of the thermometer is not much above the normal. Now it is in these protracted cases that the syphocyanide is in the greatest excess, and consequently the saliva furnishes us with a most valuable indication in respect to the prognosis of the disease.

(To be concluded.)

ON LITHOTRITY AND LITHOTOMY.

BY F. J. GANT, F.R.C.S.,
SENIOR SURGEON TO THE ROYAL FREE HOSPITAL.

HAVING recently had occasion to operate on two patients in succession for stone in the bladder—the one by lithotrity and the other by the lateral operation of lithotomy,—this unusual coincidence led me to reconsider the relative merits of these two operations, and that of the suprapubic method, for the removal of vesical calculus; at the same time reviewing the various accidents which may befall each such operation, the difficulties which may have to be encountered in their performance, and the dangers which may follow the footsteps of these procedures. I will first briefly narrate the two cases which suggested this critical survey.

CASE 1. *Lithotrity.*—Joseph D——, aged twenty-eight, had suffered from symptoms of stone in the bladder for about eight months previously to his admission to the Royal Free Hospital on March 4th, 1887. On sounding him, I found a calculus lying in the fundus of the bladder, which gave a dull sound, and was attended with an alkaline and mucous state of the urine. The diagnosis pointed to the presence of a phosphatic calculus, and that, judging from the extent of surface over which the convexity of the sound traversed, it seemed to be of large size, while the resistance offered to movement by the sound gave some estimate of its weight. The act of sounding was painful, and excited some spasmodic expulsion of urine. Operation was therefore postponed for a few days until the vesical irritability had been allayed by rest and recumbency in bed.

On March 12th lithotrity was performed. The patient having been anæsthetised, and the bladder moderately distended with warm water, the calculus was readily caught by the lithotrite, and measured nearly one inch and a half in its long diameter. It broke readily into pieces, and the fragments were successively crushed. In the process of pulverisation, the pieces were not sought by any exploration with the instrument; but, by fixing the female blade in the fundus of the bladder, and gently sliding the male blade backwards and forwards, the disturbance of the water sufficed to bring some fragment between the blades. By a half-rotatory movement of the instrument from side to side, other fragments were readily caught, lying beyond the middle area. When a quantity of detritus had accumulated, it was evacuated by a No. 15 evacuating catheter, the orifice of the urethral meatus having been incised to admit of the introduction of this instrument. Crushing and evacuation were repeated a second and a third time, the operation lasting an hour and a half, when I deemed it advisable to leave the remainder for another sitting. But it is worthy of note, that the water in the receiver of the aspirator is scarcely blood-stained throughout the operation. A gentle use of the lithotrite, in the manner explained, even for a long period, is better tolerated, and especially by an irritable bladder, than that by a more active use of the instrument, lithotrity should be finished in half the time. The patient suffered not the slightest after-symptom of any kind, feeling as comfortable as if nothing had been done, and passing urine only three or four times daily. The man was kept in bed only on account of the acute east winds.

Digitized by Google

Three-quarters of an ounce of phosphatic calculus had been thus removed without any inconvenience.

In a few days the operation was completed; with a final exploration of the bladder, which still remained irritable, even under the influence of anæsthesia. Two days afterwards, the patient being quite well, he got up at his own request. He continued under observation for a fortnight, daily taking exercise; then, no fragments having been found on carefully sounding the bladder, and being entirely free from stone symptoms, he left the hospital in good health. The total amount of phosphatic detritus, so far as it could be collected, was over an ounce in weight, and the original size of the calculus one inch and a half.

CASE 2. *Lithotomy (perineal) by the lateral operation.*—William P——, aged eighteen, had experienced symptoms of vesical calculus for a period of ten years. When admitted to the hospital (March 7th, 1887), sounding at once touched a stone, lying in the fundus of the bladder; it rang with a sound as if metallic, and was distinctly tuberculated under the point of the instrument, the stone measuring about one inch from before backwards, as indicated by the passage of the sound over its surface. I concluded that there was a hard mulberry calculus, and of more than average size. The bladder and urine were quite healthy. In this case the operation of lithotomy, and by the lateral method in the perineum, leaving the suprapubic operation out of the question, would be far more suitable than lithotrity.

On March 12th, after the previous case of lithotrity, I performed lateral lithotomy in the usual manner. But, having made the prostatic incision and seized the stone with some little trouble, as it slipped from the grasp of the forceps, I experienced a real difficulty in extracting the stone without bruising the neck of the bladder. Accordingly, I had recourse to an expedient which I strongly advocate in such cases. Passing a blunt-pointed scalpel along the inner blade of the forceps, held in the prostatic incision, I made a second rectangular or transverse incision outwards in the right half of the prostate, sufficiently to extract the stone with ease. This modification of the operation was seen to be necessary, not only from the size of the calculus, but owing to the projection of its rough surface beyond the blades of the forceps.

The after course of this case was noteworthy only on account of the absence of any unfavourable symptoms. No suprapubic pain ensued as from pelvic cellulitis, and the urine passed freely through the wound about six times in the twenty-four hours for the first two days. Thus, on the second day—usually a critical time—The report states: April 14th: urine from wound at 10 A.M., 2 P.M., 6 P.M., 8.30 P.M., 10 P.M., and 6 A.M. On the following (third) day urine was passed through the urethra and through the wound, and so on, alternating until the fifth day. Subsequently the urine again passed more and more through the wound; but from the eighth day onwards entirely per urethram. The perineal incision healed up from within, without any tenderness or fulness, and had completely closed in a fortnight. Recumbency still seemed advisable, to render the perineum firm and unyielding, the wound having been known to reopen in consequence of the patient being allowed to get up at too early a period; but the young man took gentle walking exercise in the quadrangle of the hospital for a few days, and then left quite well. The stone, a fine specimen of black mulberry oxalate of lime calculus, looked like a round rough piece of iron slag, and weighed nearly an ounce.

Choice of operation: lithotrity or lithotomy; lateral, median, or suprapubic.—Before proceeding to remove a stone from the bladder, certain clear and definite views must be held as to the *conditions* which should determine the kind of operation, seeing that the circumstances which lead to this selection will obviously affect, for better or worse, all the contingencies of difficulty and adverse consequences which are associated with the particular method, but which are referable rather to the questionable fitness of the case, and thence the prior judgment of the operator. In connexion with the relative merits of lithotrity and lithotomy, whatever method be adopted, no question can have more practical significance than with regard to the size and the density of the calculus, coupled with the state of the bladder and urinary tract throughout—the combination of factors which shall be more favourable for the performance and after safety of the one or the other of these operations. The wide difference of results in the hands of experienced operators may be thus explained, more than by circumstances incident to the individual skill of the operator.

Bigelow's method of rapid lithotrity has done much to place the crushing operation on equal terms with the cutting operation of lithotomy for the complete removal of stone from the bladder; but, if rightly interpreted in its full bearings on the question, this method has done even more to demonstrate the circumstances which should determine the surgeon's choice. The complete evacuation of stone from the bladder by a single operation of crushing, prolonged perhaps for an hour or more, as *compared* with the former method, by repeated crushings, each lasting only a few minutes, may be read in the light of a *crucial* experiment to test the tolerance of the urinary bladder for the free use of instruments or for the continued presence of stone fragments. The evidence in favour of prolonged instrumentation has not only reversed the judgment formerly held as to the supposed intolerance of the bladder for this kind of irritation, but has elicited the equally significant fact that stone chips remaining in the bladder, followed speedily by cystitis or aggravating the previous vesical inflammation, is the immediate cause of death after lithotrity. The choice of operation for the removal of stone must, therefore, be centralised in the *kind of calculus* with which the surgeon has to deal. In lithotrity, a *hard* calculus, ringing as if metallic when sounded, yields fragments more angular and irritative than those of a soft calculus—more provocative of cystitis. Unless the bladder can be most assuredly emptied of all such fragments, a hard calculus of uric acid or oxalate of lime had far better be removed by lithotomy. Of course the *size* of the stone is also an important consideration, but quite subordinate, I should say, to that of density, as a factor in lithotrity. According to my judgment, the crushing of an earthy phosphatic calculus, measuring by the lithotrite an inch and a half, would entail less bladder liabilities than the crushing of a flinty mulberry calculus of only half that size. The one squashes readily into grit as the operation proceeds; the other gives way with a sort of bang, falls into angular pieces, and then breaks into similar fragments. Any remaining chips which had perchance escaped evacuation would induce cystitis more surely than the whole amount of pulverulent matter into which the phosphatic stone had crumbled, mixing with the water into a mortar-like puddle in the bladder.

With relation to lithotomy, the *size* of the calculus is *the* element in the question which mainly determines the claims in favour of lithotrity. The dimensions of a stone may render it ill-fitted for extraction by any cutting operation. In *lateral* lithotomy, the extraction of a stone beyond a certain size, is attended with such bruising of the neck of the bladder as will almost inevitably be followed by spreading cellulitis around. On the other hand, a more than limited prostatic incision backwards might trespass beyond the fascial investment of the prostate, and lead to urinary infiltration, with the same result. But contusion of the vesical neck is more frequently responsible for a fatal issue. The *median* operation can offer only a limited access to the bladder, and allowing the extraction of a proportionately small stone, this method of cutting is out of the running, in comparison with lithotrity. Looking at lithotomy only from a stone-extraction point of view, it is here assumed that in either the lateral or the median way of approaching the bladder the path is well known, with its relations, and the operation skilfully performed. *Suprapubic* lithotomy provides for the removal of a large stone, of such size as could not be removed by lithotrity, however prolonged or repeated. But, having regard to the pathway of operation, experience has shown, and quite recently, that the bladder cannot be entered above the pubes always, without wounding the peritoneal reflexion, even when the bladder is raised by the fullest distension, almost to the point of bursting, and propped up from below by an equally distended Petersen's rectal bag. Then, again, the known risk of urinary infiltration has proved to be a not uncommon after-consequence of the suprapubic incision, and certainly should not be an after-thought in the mind of the surgeon who is about to operate by this route.

Apart from the kind of calculus, as determining the choice of operation, of less direct importance may be reckoned the state of the bladder and kidneys, cystitis depending far more on the continued presence of stone fragments after lithotrity than arising from this operation. The complete evacuation of the bladder would place the rapid method on

Digitized by Google

a level with any operation of lithotomy. So, likewise, nephritis or pyelitis, whether due to the extension of vesical inflammation up the ureters, or occurring from reflex vasomotor influence on the kidney, is alike the expression of vesical irritation. The symptoms betokening renal irritation, by rigors, lumbar pain, with uræmic blood-poisoning, proceed from the bladder, and all the significance of kidney mischief is lost in the prior question of entire removal of the calculus from the organ below.

But when, in any case, the hardness of a calculus would be adverse to lithotrity—unless the operation can be completed, and the bladder be certainly emptied of all fragments, and when the size of the calculus places it beyond lithotomy, otherwise than through the perils of the suprapubic adventure,—can the old lateral operation of lithotomy be modified and adapted for the removal of a stone, whose dimensions may require further space than usual for its extraction, without any untoward consequences? The perineal incision itself will, of course, be sufficient; and the prostatic incision may be safely extended backwards to the very neck of the bladder, notching the elastic ring, but within the boundary of the fascial investment of the prostate; the incision, thus limited, admitting readily of enlargement, by a tunneling dilatation with the finger, without dividing or rupturing the elastic ring. But the opening thus formed by this well-defined incision and dilatation may be further enlarged to twice the size by a rectangular incision from the middle of the first towards the other side of the prostate. In a prostate of average dimensions the usual lateral incision may be one inch, admitting of the extraction of a calculus which shall weigh an ounce and a half; and the rectangular incision, in the middle of the right half of the prostate, having nearly the same extent—another inch,—will provide the additional space for the extraction of a stone double the size, should the necessity arise in this stage of the operation. The valvular opening thus formed gives, therefore, ample room for the passage of a calculus as large as may be met with. This *rectangular* incision is not the incision which was practised occasionally by Martineau and Liston, who divided the right side of the prostate downwards towards the right ischial tuberosity, forming, with the similar section of the left side, a double *lateral* section of the prostate. The objection to that direction of the second incision to the right is the liability of wounding the rectum, now that the prostate is not held up by the staff, and the bowel protected also by the finger, as when in the act of making the ordinary lateral incision alone in the left half of the prostate. The semilunar prostatic incision, by the "bilateral operation" of Dupuytren, has obviously a different shape, and the downward direction of the section on either side, in using the covered double-bladed lithotome, is very liable to touch the vasa deferentia or the seminal vesicles, and emasculate the patient. Notching the margins of the ordinary left lateral incision, obliquely, above and below the "quadrilateral section" of the prostate, advocated by Vidal de Cassis, is a procedure which involves no such risk; but nickings with the knife in those situations, to ease the forceps for the extraction of a large stone, might readily cut the fascial investment of the prostate above or the rectum below. The additional space afforded by the rectangular section passing transversely across the right half of the prostate is fully equivalent to that which is given in either of these ways, and is entirely free from any danger. It is easily accomplished. When, in the extraction of a large stone, the forceps is found to be fixed somewhat firmly in the ordinary lateral opening in the prostate, the second cut can be made by sliding a blunt-pointed knife along the convexity of the inner blade, and carrying it outwards, not downwards, in the middle of the right half of the prostate. If there be any doubt as to the bearing of the blade, a little traction with the forceps will make the prostate bulge forwards sufficiently to bring that part actually into view in a perineum of the ordinary depth. By this second transverse incision bruising of the vesical neck is prevented, the risk of urinary infiltration from a too free left lateral incision in the backward direction is avoided, and the extraction of the stone is effected without fracture and splintering in the bladder, or in drawing it through the prostate.

By the operation of lithotrity large stones of the hardest kind have been pulverised, and the bladder completely emptied. That operation may be credited in Freyer's practice with having thus got rid of calculi formed of uric acid and oxalate of lime, each weighing more than three ounces. But these are quite exceptional cases, and in the hands of an exceptional lithotritist. Success in crushing and evacuating such calculi might well place some other operators in mourning. The average lithotritist, tackling either of those hardened sinners, would certainly have left some portion of the enemy in the bladder; ay, and even after a second attack, an angular fragment or two might still be lodged. When the surgeon, who is about equally apt in crushing or cutting, has to encounter a big, brazen mulberry calculus, or its almost as formidable uric acid rival, instead of spending an hour and a half or longer in lithotrity, without then clearing out the bladder, I would recommend him to try lateral lithotomy, with the additional rectangular incision of the prostate to the right side, and capture the enemy in a few minutes.

I may take another opportunity of referring to the difficulties and dangers pertaining to lithotrity and lithotomy in the various methods of operation.

Connaught-square, W.

A MEDIAN LITHOTOMY.

By REGINALD HARRISON, F.R.C.S.,
SURGEON TO THE LIVERPOOL ROYAL INFIRMARY.

THE recent movement to revive the suprapubic operation for stone in the bladder, under somewhat altered circumstances, has been doubtless prompted with the view of diminishing the mortality connected with the removal of those stones from the bladder which cannot be effected by crushing, and of substituting an operation which is free from the difficulties and risks which, either rightly or wrongly, have been associated with lateral lithotomy. That there are grounds for possessing an alternative is evident from a study of some statistics and records of the latter operation. That the lateral method for stone in adults has been found to be a proceeding attended with a considerable degree of fatality, reaching in some instances, it is stated, to a death-rate of 35 per cent., there can be no doubt. Further, records of this operation show that the mortality has arisen very largely out of complications having an evident relation to the difficulties with which the operation was performed. For instance, a well-executed lateral operation where everything is straightforward is about the safest operation of any magnitude in surgery; and in proportion with the degree of deviation from the standard that circumstances render inevitable may its fatality be measured. In proof of this let me mention the chief early causes of death after lithotomy. Hæmorrhage, primary and secondary; cellulitis and peritonitis arising from damage done by the knife, as when the latter is allowed to miss or leave the staff and to pass behind or through the bladder, not mentioning the rectum; rupture of the urethra and failure to enter the bladder, as when these parts are telescoped by the finger of the operator; and, lastly, sepsis. With the exception of the last-mentioned cause, which is largely determined by the nature of the incisions made, probably all the others are avoidable, and seldom occur save in connexion with an operation the doing of which might be improved upon. Apart, however, from these difficulties and contingencies, there is a necessity for carefully considering our means of removing stones from the bladder by the frequency with which recurrences take place after lithotrity, even when the operation has been practised by experienced hands. Such recurrences have been recently stated as amounting to about 13 per cent.

When we consider the rarity of stone relapses after lithotomy, as compared with lithotrity, we have the best reason for critically studying the former operation with the view of rendering it simple and efficient. I think it will be generally admitted that the easiest and simplest method of entering the bladder, say for the purpose of exploring it with the finger, is that known as median perineal urethrotomy, or incorrectly as median cystotomy. By this plan the finger may be readily passed into the bladder without risk. As I have now practised this operation for the relief of cystitis, for the exploration of tumours of the bladder and prostate, for prostatotomy and prostatectomy, a very considerable number of times, I think my experience has

Digitized by Google

been sufficient to warrant this statement. But though the finger may thus be readily introduced into the bladder, as well as sounds and forceps, for further exploration, it will be urged that nothing of any size can be withdrawn with safety through such a limited opening. Even admitting the fullest amount of dilatation, a uric acid stone of half an ounce in weight could not be withdrawn without such an amount of dragging and tearing as to render a fatal result inevitable. But this exploratory opening, which is essentially the old median cystotomy, can be easily and safely adopted for the removal of larger stones—say, up to six-ounce urate or oxalate ones. The demonstration of this point may be regarded as the object of this paper. During the course of a number of operations, undertaken for the relief of symptoms due to a large prostate, I found it was quite feasible and easy to obtain as free an opening into the bladder by a median incision along the urethra and floor of the prostate, as by the ordinary lateral operation for stone. To effect this, the following additions to the operation known as median perineal urethrotomy for the exploration of the bladder are necessary. The finger having thus been passed into the bladder by the side of the staff, the opening is extended in the following manner. In the first place, the membranous urethra is slit up along its floor on the staff by a curved probe-pointed bistoury; in this incision may be included more or less of the perineum according to circumstances. Any bleeding vessel may be tied before proceeding further. The deep incision is then made by passing the curved probe-pointed bistoury by the side of the index finger well into the bladder. The staff may now be withdrawn. The blade of the knife is turned downwards towards the rectum, and the floor of the prostate divided from within outwards, commencing at the depression, which exists more or less in all male adults just within the orifice of the urethra. The incision thus made with the knife may be deepened down to the capsule merely by the firm pressure of the index finger downwards. In this way I have been able to make as free an opening into the bladder nearly along the median line of the body as a lateral lithotomy will permit of. This can be readily tested on the dead subject.

Many operators, I believe, will find this an easier way of opening the bladder freely for the purpose of removing stones, which, without the modification mentioned, could only be effected either by lateral or suprapubic cystotomy. It may be urged that the downward incision of the prostate necessarily endangers the integrity of the seminal openings. I am not aware that there is any reliable evidence in favour of such an objection, at least so far as causing a permanent inconvenience is concerned; at all events, I should have no hesitation in saying that, if an operator for stone feels that he can perform a median operation with the adaptation just described more safely than a lateral, he had better risk the seminal apparatus than the life of his patient. The operation described, though planned for and practised chiefly on adults, is capable of extension to male children, should the ordinary median lithotomy not suffice for the size of the stone, as the floor of the urethra and rudimentary prostate may be divided in a downward direction with a bistoury. I have sometimes heard it stated that the lateral operation in children is not only difficult, but dangerous, by reason of the risk there is of rupturing the urethra in endeavouring to enter the staff and dilate the canal, and then pushing on everything, including the bladder, before the tip of the finger. In this way there can be no doubt that the bladder has not been entered at all, and the way to it irretrievably lost. In connexion with this point, I would remark that such a risk is usually incurred by a misconception as to the mechanism of lateral lithotomy. When the groove in the staff has been exposed by the first incision, no attempt should be made to force the finger into the bladder until the point of the knife has been run along the groove towards the bladder for such a distance as to allow the finger of the left hand to be *put* into the bladder, and not pushed. The way into the bladder should be cut with the knife, and not bored with the finger. Where due regard is given to this point, it is almost impossible, even in a child of tender age, either to rupture the urethra or to push the parts in front of the index finger. So much stress has been laid upon dilatation by some authors as a necessary part of lithotomy that I have taken this opportunity of referring to it as an error that is sure sooner or later to be the cause of embarrassment to those who place any reliance upon it. Further, the deep incision I advocate in connexion with this method of performing median lithotomy assimilates it with the lateral proceeding not only in providing freedom of access to and exit from the bladder, but in being followed by an incontinent flow of urine which continues for some days. An ordinary median perineal lithotomy will not drain effectually without a drainage tube; this it is often desirable to dispense with, especially in chronically inflamed and ill-shaped bladders where the urine is offensive. This is an important safeguard against sepsis. However perfect the median operation for stone might be so far as the withdrawal of the calculus is concerned, I should set it aside unless it provided for incontinent urine drainage, which might be depended upon to last for at least some days. The vertical division of the prostate muscle was advocated by Vacca[1] at the commencement of the century, but chiefly in connexion with a recto-vesical operation which has now become obsolete. A reference to Vacca's plates will show that he made his incision through the floor of the prostate, a little to one side of the median line, with the view of avoiding the seminal openings. In the course of a number of operations on the obstructing prostate,[2] I soon became convinced that it was almost impossible to make a safe and satisfactory division of the prostate, whether normal or enlarged, from a median urethrotomy, except in a direction from within outwards as I have now described; and, further, that the full effects of such a section could not be fully appreciated as a means of free access into the bladder, unless it was accompanied with the division along its floor of the membranous urethra, as the latter structure, in conjuction with the bulbous portion of the canal, seemed to arch in the outlet from the bladder, and thus to restrict manipulations.

The advantages of the median method I have described may be summed up as follows: 1st. That an incision is made into the bladder along the antero-posterior axis of the outlet from the pelvis which gives as much, if not more, room for manipulation as the lateral incision. 2. That with such an incision the liability to hæmorrhage is less, whilst the facility for getting at any bleeding point is increased. 3. That the movements of the knife in one hand are from the beginning to the end of the operation under the direction and control of the index finger of the opposite hand. 4. That it entirely removes the dragging and tearing of the old median operation should the stone prove a large one, and therefore it adapts the median procedure to a wider range of stone, as well as of tumour cases. 5. That, like after lateral lithotomy, a similar state of temporary incontinence of urine is provided for, and thus thorough drainage is secured by a dependent opening, should this be desirable.

I would observe that we have been too much accustomed to draw our ideas relative to the section of the prostate in lithotomy from the contracted appearance presented by the part after death, and which rarely, if ever, presents itself to the lithotomist. As a matter of fact, unless the bladder is absolutely empty, the prostate is disposed as a circular cone of muscle with its apex directed forwards. In connexion with the making of the deep incision through the prostate in a direction from within outwards on a guide, it would appear from the surgical lectures of Dr. A. Monro of Edinburgh that Frère Come, a successful lithotomist of the last century, was in the habit of incising in this way, thus avoiding many of the dangers which befell his contemporaries. I will now illustrate some of these points by the following case, where the recovery of the patient, notwithstanding his feebleness and complications, was remarkably rapid and in other respects uneventful.

C. B——, stated to be fifty-six years of age, though looking about seventy, was admitted into the Royal Infirmary on March 9th, 1887, having been sent to me by Dr. M. J. Campbell. He had previously been in hospital for what was stated to be an impassable stricture of some years' standing. He presented the appearance mentally and physically of a feeble old man. I found him suffering from a very narrow long stricture in front of the bulb, a false passage of some length and far more easily entered than the natural canal, a stone in the urethra behind the stricture, one or more stones in the bladder, and chronic cystitis. He passed his urine incontinently in drops, and his clothes and bedding were constantly soaked with ammoniacal urine. Having regard to his general feeble condition, as well as the varied nature of his symptoms, it was difficult

[1] Della Litotomia. Pisa, 1825.
[2] Trans. Internat. Med. Congress, Copenhagen, 1884.

Digitized by Google

to determine what was best to be done, especially having in view the probability of his kidneys and ureters being also involved. A free median incision into the bladder, such as I have described, seemed to offer the best solution with the least risk. Further, should the strictured urethra prove such as to render a permanent median perineal opening desirable, this could be provided for by the median operation. On March 29th, Dr. Paul Rodet, of Vittel, and Dr. Wilson, of Boston, U.S.A., being present, the patient was etherised, and the stricture divulsed so as to allow the passage of a medium-sized grooved staff into the bladder. He was then placed in the lithotomy position, when I performed a median urethrotomy, and extracted a uric acid calculus about the size of a cobnut, which was wedged in behind the stricture. I then slit up the floor of the membranous urethra, including a mass of cicatricial tissue which constituted the stricture. Passing my finger on into the bladder, I then divided the somewhat large prostate directly backwards with a curved probe-pointed bistoury from within outwards, completing my incision to the utmost limits of the prostatic capsule by the pressure of my index finger. In this way I had made an opening into the bladder in the median line which would readily admit my three fingers. Forceps were then passed into the bladder, and I extracted two calculi, one uric acid and the other phosphatic, about the size of cobnuts, and in addition a considerable quantity of soft, putty-like phosphatic incrustation. No vessels were tied, and the patient certainly did not lose an ounce of blood, an object which I was desirous of obtaining. I could have removed through this opening, with ordinary lithotomy forceps, a hard stone of at least six ounces in weight. As a precaution against any bleeding following, a large double drainage tube was introduced, and the wound in the perineum above and below it closed with sutures so as to make the tube fit with some tightness. The patient was then removed to bed, the whole of the proceedings only occupying a few minutes. The patient's convalescence has been uninterrupted, and on April 10th he commenced to get up and move about. The urine for the first eight days was passed incontinently by the wound, the drainage tube being removed on the third day. On April 14th he was able to go out for exercise, as control over the urine, though almost entirely passed by the perineal wound, had in a great measure returned. I think it is extremely probable that the perineal opening will have to be retained as a permanent vent for the urine, as the condition of the urethra in front, from long-standing stricture, is unpromising. A medium-sized whip bougie is passed daily along the whole length of the urethra. Apart, however, from this consideration, the case may be taken as fairly illustrating this method of operating and the circumstances under which it might be undertaken. Here it was the only way of getting over the difficulties I had to face without exposing the patient to far more serious risk.

As already stated in the columns of THE LANCET,[3] I have no reason whatever to find fault with the operation of lateral lithotomy. I have now practised it considerably over one hundred times, with no mortality in children, and with a death-rate in adults of about one in twelve. On the other hand, understanding why lateral lithotomy can never be regarded as universally acceptable, I think it is desirable that we should be provided with efficient alternatives.

Liverpool.

THREE CASES OF
SUPRAPUBIC LITHOTOMY.

BY WALTER WHITEHEAD, F.R.C.S.E., F.R.S. EDIN.,
SURGEON TO THE MANCHESTER ROYAL INFIRMARY, LECTURER ON CLINICAL SURGERY AT OWENS COLLEGE.

FOR the purpose of contributing to the number of modern cases of suprapubic lithotomy, I have written out the following notes, and added a few remarks suggested by my experience.

CASE I.—J. H——, aged fifty-one, a publican from Oldham, was sent to me in June, 1884, by Dr. Lacey, suffering from stone in the bladder. He declined operation. The following month he again called and produced a small calculus which had been expelled per urethram, stating that all his symptoms had immediately disappeared. Albumen, which had been present in the urine formerly, was now absent. I neither saw nor heard anything of him again until Jan. 29th of this year, when he was again sent to me by Dr. Lacey. I observed a very marked change in his appearance. From being a fine, stout, and powerful man, he had become flabby and feeble, short of breath, and affected with a hacking troublesome cough. He had all the characteristic symptoms of stone in the bladder, with almost constant desire to micturate. He was admitted into the Surgical Home, Greenheys, on Feb. 3rd, 1886, and three days afterwards an unsuccessful attempt was made to crush the stone; for although the calculus was easily and frequently grasped by the largest and most powerful lithotrite, it was evident that the instrument was not constructed for so large a stone, as the screw gear did not come into action when the blades were fully separated. It was decided to postpone any further operation for some days, and in the meantime decide between the merits of perineal and suprapubic lithotomy. On the evening of Feb. 9th, he contracted a chill whilst returning to bed after a hot bath, and on the following morning when we (Mr. Southam, Dr. Lacey, Dr. Thorburn, and myself) assembled to operate, his temperature registering 102·4°, a further postponement of the operation was naturally our first determination, but this was finally abandoned. Suprapubic lithotomy having been decided upon, the operation was conducted in the following manner:—The patient was placed on the table in a horizontal position and the A.C.E. mixture administered. The pubes were shaved. A No. 12 silver catheter was introduced into the bladder and the urine withdrawn; twelve ounces of a weak solution of boracic acid were injected into the bladder and the catheter withdrawn, and the base of the penis ligatured with a soft No. 8 elastic indiarubber catheter. An indiarubber bag, capable of holding sixteen ounces of fluid, well lubricated with vaseline, was introduced into the rectum above the sphincters and injected with twelve ounces of water. An incision was made in the median line of the abdomen, commencing three inches above and terminating at the upper border of the symphysis pubis. A dissection was made between the recti, and through the transversalis fascia down to the perivesical fat, and this separated, the handel of a scalpel being principally used for this purpose. At this stage of the operation some doubt was entertained as to the identity of what was supposed to be the bladder, which had in reality ascended into the wound and overlapped the symphysis; this, however, was immediately corrected by the reintroduction of the catheter, without allowing any fluid to escape, and by projecting the beak above the symphysis. The catheter was removed, and the ligature again tightened. The bladder was then punctured, without, unfortunately, first taking the precaution of securing it, either with a pair of forceps, or, still better perhaps, with two ligatures passed at suitable intervals through the entire thickness of the presenting surface. This was an oversight which ought never to have taken place, as all the fluid commenced to stream out and the bladder to collapse and sink out of sight, and it was with no little uncertainty the bladder was again picked up and the puncture found. Had the finger instead of the eye been relied upon under the circumstances, it is conceivable that lamentable results might have ultimately followed through detaching the cellular tissue surrounding the neck of the bladder in the endeavour to recover the lost opening, which would have afforded every facility for the infiltration of urine. Having recovered the bladder and secured the opening with artery forceps, scissors were introduced, and by expanding the blades the incision was enlarged longitudinally, sufficiently to admit one and then a second finger. The stone was at once felt and easily removed by means of an ordinary pair of lithotomy forceps. After the bag in the rectum had been removed the operation was completed. Nothing further was done or required, in a surgical sense, during the nine days the man lived. The urine, which was copious, escaped through the wound and was absorbed by pads of absorbent wool conveniently arranged below the wound. No excoriation followed or threatened. No urine passed by the penis, and neither catheter nor drainage tube was used after the first few hours. The patient, who was almost doomed to succumb from the commencement, died from double pneumonia, which was evidently in the incipient stage prior to the operation. The stone was composed of uric acid. It weighed 3½ oz., and measured 2½ in. by 2 in., or 7½ in. in circumference.

CASE 2.—J. W——, male, aged forty-two, was admitted to

[3] April 10th, 1886.

Digitized by Google

the Manchester Royal Infirmary on Dec. 8th, 1884. He is a healthy-looking but slightly made man, and gives a good account of his family history and general health up to twelve years ago. Since then he had frequent attacks of renal colic, which had, however, usually yielded to ordinary methods of treatment. Eighteen months ago he first experienced pain at the end of the penis, and he passed some gravel. Since then there have been occasional attacks of renal colic, and he has passed gravel on several occasions. He has also been troubled by frequency of micturition, which often disturbed him six or seven times in the night. His pain has always been aggravated by any shaking. During the last nine months he has often had hæmaturia. There have been no symptoms of cystitis. On admission, he complained of the above symptoms. The urine was acid; sp. gr. 1015; it contained no albumen and no deposits. The bladder was explored by a Thompson's sound, and a stone was found, the longest diameter of which appeared to be about three-quarters of an inch. On Dec. 12th, 1884, the operation of left lateral lithotomy was performed in the usual manner, the only difficulty encountered being in the extraction of the stone, which was oblong in shape, being about ¾ in. long and ½ in. broad. No tube was introduced into the wound. The only incident in the progress of the case was that the wound became filled with blood clot, remaining in this condition for some forty-eight hours, and necessitating the use of the catheter to relieve the bladder. On the second day urine commenced to flow through the wound, and thereafter continued to do so. The wound healed well, and when the patient went home on Jan. 5th, 1885, was almost healed, although a small quantity of urine still came through it. This soon ceased after his return home, and he remained well. He was readmitted on March 31st, 1886, complaining of shooting pains in the glans penis and perineum, especially at night or during exercise, this pain being most intense for about five minutes after micturition. During the act of passing urine there was frequently sudden stoppage with pain, but the flow soon recommenced. Exploration of the bladder showed the presence of a stone, and on rectal examination there was found considerable enlargement of the prostate. The patient was much weaker than when last admitted, and looked thin and worn. On April 2nd I attempted to perform the operation of suprapubic lithotomy, in the presence of Mr. Chiene of Edinburgh, Mr. Lund, and the members of the surgical staff of the Manchester Infirmary. On attempting to pass a catheter into the bladder with a view to injecting it, the instrument entered a false passage, and all attempts to introduce it proved futile. Being unwilling to abandon the operation, I placed one of Sir H. Thompson's bags in the rectum, which was distended with ten ounces of water. A vertical incision, three inches long, was now made in the linea alba, over the pubes, and the structures being dissected down to and through the fascia between the recti, the bladder was sought for. As, however, it was found impossible to define this organ without running a great risk of injuring the peritoneum, the completion of the operation was postponed, the wound being thoroughly dusted with iodoform and left open. The wound continued healthy, but the patient suffered much from pain in the bladder, owing to his cystitis, for which was prescribed a mixture of hyoscyamus, buchu, and liq. potassæ. The pulse was very rapid, irregular, and so weak as to be at times scarcely perceptible. On April 10th, eight days after the first attempt, the patient was again placed under chloroform, and an attempt made to introduce a catheter into the bladder. This again failed, but after some trouble a ferret was passed, and a catheter, having an eye at the extremity, was slipped in over it. The bladder was then injected with six ounces of boracic lotion, and the rectum distended as before. The divided structures being held aside, the bladder was now, without difficulty, seen presenting in the wound, and was secured by passing through it on each side a ligature held in a handled needle. Between these the bladder was opened with a knife and a director, and the finger and then a pair of lithotomy forceps introduced, and the stone grasped and extracted without difficulty. The wound was left open, dusted with iodoform, and plugged with absorbent cotton wool, which was changed every half hour. No catheter was placed in the urethra, nor a tube in the wound. The wound remained absolutely healthy-looking, the urine which came through it being absorbed by the cotton wool. The patient's weakness, however, increased, the pulse being always rapid, weak, and irregular, often imperceptible. Stimulants were administered a week after the operation; then a low form of delirium set in, with much restlessness. This delirium continued almost constantly for a month, but eventually passed off entirely. Urine came away entirely by the wound until May 1st, three weeks after the operation, when, for the first time, some passed per urethram. After this the wound began to close up rapidly, and was entirely closed by May 16th. On the 27th the patient was discharged well, and has since reported himself as in good health.

CASE 3.—J. M——, male, aged fifty-three, came under my care about the end of April, 1886, giving the following history. In August of last year he had several rigors, followed by the discharge of dark brown urine with frequent micturition and pain at the umbilicus. He was then attended by Mr. Cartmel. Occasional hæmaturia continued, and especially after any jolting there was pain at the umbilicus and passage of blood in the urine, but never any pain in the bladder or penis. On one or two occasions there was, during micturition, a sudden stoppage in the flow, causing much straining and pain. When I saw the patient I found a stone in the bladder, and attempted to perform lateral perineal lithotomy, but without success, owing to the depth of the perineum rendering it impossible to reach the calculus. With a view to performing suprapubic lithotomy, I admitted him to the Manchester Royal Infirmary on May 22nd. On admission he presented the same symptoms as before the first operation a week previously, and he had, of course, an opening from the perineum into the urethra. The general condition was very good. The operation was performed on May 23rd. On examination the bladder was found to be unusually large, dulness extending to within two inches of the umbilicus. Neither the bladder nor the rectum was distended. A staff was introduced into the bladder (through the perineal wound) and its point rendered prominent just above the pubes. An incision 2½ in. long was then made in the middle line above the pubes, and carried down until the bladder was exposed on the end of the staff. It was here torn open, and the small opening thus made enlarged by stretching with the fingers. There was then no difficulty in introducing two fingers and seizing and extracting the calculus, which was encysted in a pouch in the anterior wall. The stone was uric acid, oval in shape, flattened on the sides, and about 1½ in. long by ¾ in. wide. The wound, which gaped considerably, was left open and painted with a mixture of compound tincture of benzoin and an ethereal solution of iodoform, then dusted with iodoform and stuffed with iodoform gauze. The patient was allowed to lie on his back, the whole of the lower part of the abdomen being covered with absorbent cotton wool, which effectually soaked up the urine as fast as it came through the wound, so that no irritation of the skin was caused. On June 4th urine ceased to flow through the perineal opening, but still came freely from that above the pubes. On June 9th the urine was found to be alkaline, and there was a phosphatic deposit on the surfaces of the wound, which gave some trouble, and which was met by the internal administration of ammon. benzoas, with local use of dilute hydrochloric acid. From this date the patient's condition became gradually worse. The urine remained alkaline, and he developed the "typhoid" symptoms of surgical kidney. During August he complained of pain in the left shoulder, probably pyæmic. The temperature was high and irregular. To the end all urine passed by the wound, the flow per urethram never being re-established. The patient died on August 31st.

Remarks.—The fact that two out of the three cases of suprapubic lithotomy recorded proved fatal must not be regarded with undue prejudice against the operation. I am satisfied that in Cases 1 and 2 the patients would have died whichever operation had been selected. The size of the stone in the first case left no alternative, and in the third case suprapubic lithotomy was only resorted to after perineal lithotomy had failed. A practical lesson can be learned from Case 2. The man had undergone perineal lithotomy two years previously, and his recovery was complete in nineteen days, whereas after suprapubic lithotomy forty-eight days were required to gain convalescence. The three cases illustrate three conditions which render suprapubic lithotomy the only operation available: the large size of the stone in one case, an impediment to the introduction of a staff in another, and an encysted calculus in the third. During the last two years I have had an unusually large number of patients suffering from stone in the bladder, and these are only instances in which I have felt warranted in adopting the suprapubic operation, as I am

Digitized by Google

at present quite satisfied with the success which I have had during twenty years' practice from perineal lithotomy and litholapaxy. I regard rectal distension as quite unnecessary, and not unattended with danger; in Case 1 the use of the rectal bag was followed by profuse hæmorrhage and subsequent muco-purulent discharge. Pending much stronger evidence than that which has hitherto been advanced in favour of the high operation, I shall continue to crush all stones capable of being crushed both in males and females, either in youth or adult life. I shall perform perineal lithotomy in cases not amenable to crushing, unless associated with some complication rendering it impossible to complete that operation, and I shall reserve suprapubic lithotomy for such cases, and for stones estimated to exceed three ounces in weight. These conclusions will, I believe, be generally shared by surgeons who have had large experiences in the various operations for the removal of vesical calculi.

Manchester.

RESULTS OF CICATRISING PROCESSES IN THE NEIGHBOURHOOD OF THE PORTAL FISSURE.

BY HENRY F. A. GOODRIDGE, M.D., F.R.C.P.,
SENIOR PHYSICIAN TO THE ROYAL UNITED HOSPITAL, BATH.

IT is well known that structures which derive their blood supply from vessels that pass through a cicatrix, or that traverse the area of a cicatrising process, are liable to undergo atrophy, and that this is due to the contractile property of the cicatricial tissue causing narrowing and diminution of calibre of the supplying vessels. The facts have been observed on the surface of the body, and, indeed, have been turned to good account in some instances in the practice of surgery. But it is not so generally recognised that similar secondary results may under certain circumstances follow cicatrisation occurring in internal parts, and prove serious drawbacks to the healing process. The events that take place here, and their relation to one another, are out of the sphere of direct observation, and the opportunity of tracing them by other methods is comparatively rare. Conceiving that the two cases about to be related afford such opportunity, I propose in this paper to invite attention to the subject, and to submit some pathological considerations in connexion therewith.

In the case of a small superficial ulcer of the stomach, the loss of mucous membrane at the spot with a trifling scar remaining is about the worst evil that can ensue. But it is far otherwise with a large, deep, and long-standing ulcer occupying the usual situation of the "chronic ulcer of the stomach." Besides stenosis of orifices, deformity of the organ is commonly noticed by writers as resulting from the cicatrisation of such an ulcer; it is rather with indirect, but not less important, results of the same that we are now concerned. It has happened to me in the course of my hospital practice to have a case of the latter class repeatedly under my care during a period of nine years extending from the first commencement of symptoms to the fatal termination, and then inspection of the anatomical condition was obtained. The following is a summary of the clinical history.

The patient, A. M——, was a lady's maid, aged thirty in January, 1866, when she was first admitted into hospital. She was moderately tall, of slender figure, and of pale complexion; she had two phthisical brothers, but said that her own health previously had been good. She had been suffering for three weeks from constant and severe vomiting after food, and from pain at the epigastrium, which was relieved, but not removed, by the vomiting; there was tenderness on pressure in the same locality. Her pulse was small and weak, her tongue pale and moist, her bowels sluggish, and her catamenia scanty. Under absolute rest, restricted diet, and nitrate of silver in half-grain doses, with a blister to the epigastrium, and an occasional enema, the symptoms speedily subsided; and with the substitution of iron and hydrocyanic acid, and a more liberal but still regulated diet, she made good progress, so that in the April following she was discharged "convalescent." In September, 1868, she was readmitted. She stated that shortly after she left the hospital she had a return of the symptoms, had to give up her situation in consequence, and had not been well since. The epigastric pain was very severe, and disturbed her sleep. Her catamenia had been absent for three months. She was put upon similar treatment. She vomited only two or three times during her stay, the pain subsided, the catamenia reappeared, and she was discharged convalescent in the ensuing December. She now had some months of comparative, though not entire, freedom from complaint, and resumed domestic service. In the autumn of 1869 she caught cold at a catamenial period, whereupon this function became completely suppressed. The epigastric pain returned, and she soon began to lose flesh and strength. She attended as an out-patient, but, no benefit accruing, she was admitted into the wards again in May, 1871. She was now in a much more pronounced state of anæmia than heretofore. Epigastric pain, increased after food and disturbing her nights, was still her chief trouble, and there was the local tenderness on pressure as before. Omitting on this occasion the nitrate of silver, she had iron given her at once, and solution of sulphate of atropine was used hypodermically as an anodyne. She soon responded to this treatment, gained nearly a stone in weight in six weeks, and went out convalescent in July following. In February, 1872, she returned, stating that three weeks previously she had vomited blood to the amount of one pint. She was very anæmic, and there was marked exacerbation of the old symptoms. Her catamenia had now been absent for sixteen months. The sickness increasing, in spite of the treatment which succeeded on the preceding occasion, she was given nitrate of silver again in half-grain doses, and with good result. On resuming the iron, flying blisters were applied to the epigastrium and dressed with morphia ointment. Although bad fits of epigastric pain not unfrequently recurred, and she had now and then sickness, her appetite increased, she began to get up a little, she improved considerably in looks, and in April following was discharged relieved. Her history for the next two years and upwards was one of attendance off and on as an out-patient. She was admitted into hospital for the fifth time in September, 1874. Her condition at this date was urgent; her pallor and emaciation were both alike conspicuous. She had had a short time previously a recurrence of vomiting of blood; her pain in the epigastrium, increased after food as before, went right through to her back and interfered greatly with her sleep; she generally vomited after her meals, though at various intervals, and this brought a little ease. The existence of considerable dilatation of the stomach was now detected, and the vomited matters were found to contain sarcinæ. There was no response to treatment that formerly succeeded, nor to some other that was tried. Hypodermic morphia as an anodyne, with or without atropine combined, gave but very temporary relief. She was almost incessantly harassed with pain and sickness. On Oct. 16th she vomited dark grumous matter in which red blood discs were abundant. There were some little fluctuations in her condition afterwards, but on Oct. 30th she had similar hæmorrhagic vomit with melænic stools, and, this persisting, she gradually became exhausted, and died on Nov. 1st.

Necropsy, thirty-three hours after death.—The stomach was found occupying the area traced out upon the abdominal parietes during life. It had several adhesions. First, it was inseparably adherent at the small curvature to the under surface of the right lobe of the liver by dense opaque neoplastic tissue, which occupied for the most part the small omentum. Another adhesion was to the pancreas and duodenum in its inferior transverse portion; and a third was to the left kidney, where also a very dense fibro-cartilage-like layer was present. There were slight adhesions to the spleen and to the diaphragm. The stomach at the same time exhibited a well-marked hour-glass contraction. The effect of the latter, as appeared on laying open the interior, was to convert the pyloric segment into a separate sac, which was entered by a quasi-orifice of about the size of a crown-piece. A large irregular stellate cicatrix was discovered at the spot near the small curvature where externally was the dense adhesion to the liver; two or three small superficial ulcers were present near it. The mucous lining of this part was much puckered. At the fundus corresponding to the kidney adhesion was a large somewhat oval-shaped ulcer; it was between four and five inches in length; its floor was constituted of the peritoneal coat, shreddy débris of muscular fibre, and some vessels traversing it. Its margin showed no trace of any reparative action, nor did that of any of the smaller ulcers present. There were several little deposits of melanic pigment in the vicinity

Digitized by Google

of this ulcer, with some increased vascularity of the mucous surface, and sundry small ulcers and erosions. The pyloric segment, which, as before observed, formed a separate compartment, included the right half nearly of the great curvature, and was the healthiest portion of the organ, being quite free from ulceration. The pylorus was normal. The total capacity of the stomach was greatly augmented; it was generally in a state of chronic catarrh, and it contained some of the melænic matter which was vomited during the last days of life, but no coagula. The duodenum was considerably dilated and contorted, the adhesion of the stomach to it just at its termination having apparently produced some constriction of the gut there; it also contained melænic matter. The liver had some slight adhesions of its convex surface; its texture was so friable that it broke under the smallest pressure—indeed the organ could not be handled without its giving way; the texture was also dry and granular. It weighed 32½ oz. There was little or no bile in the gall-bladder. The spleen weighed 7 oz., and was pulpy. Except an old adhesion of the upper lobe of the left lung, there was nothing noteworthy elsewhere. On closer examination of the gastro-hepatic adhesion, it was found that the hepatic artery and some branches of the coronary artery lay very much in the focus of the dense neoplastic tissue, and the hepatic artery was distinctly observed to undergo an abrupt diminution in its calibre.

Proceeding now to remark on the pathological events in the foregoing case and to trace their connexion, the cicatrix found in the patient's stomach is obviously the first thing to claim attention. The characters of this cicatrix clearly denote that the pre-existing ulcer was a large one, and that in its extension in depth and progress outwards, having set up adhesive inflammation in the peritoneum, it came to have a thick floor of new tissue, if, indeed, it did not actually invade the contiguous portion of the liver. From the clinical record it is hardly less evident that the ulcer was one of long standing, and in the process of its healing underwent interruptions and relapses. The marked hour-glass deformity of the organ itself attests the magnitude of the lesion and the abundance of contractile cicatricial tissue. Secondly, we observe that, although there were several small ulcers elsewhere in the stomach, and one pretty large one, there was no appearance of reparative action in any of them; whence, I think, we may infer that these several ulcers were not in existence when the one above referred to cicatrised, but must have originated at a later period. Thirdly, we find that the hepatic artery and certain branches of the coronary were for a portion of their course involved in the dense neoplastic tissue which united the stomach and liver together in the site of the same cicatrix, which occupied, in fact, the small omentum. In seeking to understand how this came to pass, we must, I think, bear in mind that, besides the cicatricial fibroid tissue repairing the breach in the gastric wall, there were the products of the inflammatory process excited in the adjacent serous membrane, and rekindled with every relapse of ulceration; so that, with exuberant plastic material, the ultimate result, when at length reparation was consummated and the contractile property of the new tissue had come fully into play, would be a lumpy mass in which the normal relation of parts would be very much disturbed and the anatomical detail difficult to make out. The hepatic artery, however, was unmistakably identified, and it was found to be abruptly obstructed. Assuming that the liver is dependent upon this artery for its common nutrition, its condition corresponded; it was much under weight, and its texture was so friable, its cohesion so impaired, that it could not be handled without giving way. But, in reference to the secondary ulcers observed on the mucous surface of the stomach, and which showed no reparative action, may we not conclude that they owed their origin, in part at least, to a similar constriction of the branches of the coronary artery causing impaired nutrition in the sphere of their distribution? Our next point would seem especially to favour this conclusion. Fourthly, the portion of the stomach included within the pyloric sac (as, for convenience sake, we may call it) was found to be entirely free from ulceration; it was the healthiest portion of the organ. Now, this, we know, is just the portion that receives its blood supply, not from the coronary artery, but from the gastro-duodenalis, a branch of the hepatic artery, given off before this latter enters the small omentum, and therefore in the present instance before it was subjected to any constricting influence.

(To be concluded).

THE OCCURRENCE OF MENORRHAGIA OR METRORRHAGIA DURING THE FEBRILE STATE.

BY ALFRED MANTLE, M.D.

IN bringing before the notice of the profession the subject of menorrhagia or metrorrhagia as occurring during a febrile attack, I may at the outset say that my purpose in doing so is for the consideration of the treatment of such cases when the circumstances of some demand treatment. It is necessary to make this proviso, because most certainly the majority of cases of menorrhagia or metrorrhagia occurring during a febrile disease require no treatment; for the loss of blood may be considered to have a salutary effect upon the disease, and nature is probably doing what the practitioner of a generation ago considered the right course of treatment in all febrile diseases.

It is not an infrequent occurrence for zymotic diseases to be ushered in with hæmorrhage. This is frequently observed in the young when scarlatina or measles is making its appearance, at which time the hæmorrhage is most often seen to take place from the nasal mucous membrane. In older patients epistaxis or hæmatemesis is occasionally observed at the outset or early in the course of the fever; whilst in others—and this is particularly the case with measles, scarlatina, small-pox, typhus, typhoid, yellow, and intermittent fevers, and sometimes in pneumonia—the hæmorrhage shows itself from the mucous membrane of the uterus. In some cases this may mean nothing more than the normal process of menstruation taking place, which may or may not have been hastened a few days by the pyrexial attack, and the amount of blood lost may not necessarily be in excess; but in the strong and plethoric, and particularly in small-pox, typhus, typhoid, and yellow fever, the loss may sometimes be excessive and perilous, demanding active treatment. In other instances the hæmorrhage is quite unassociated with the normal menstrual act, when such cases may be said to be ordinary cases of uterine hæmorrhage or metrorrhagia induced by the febrile condition. I believe, however, that by far the largest number of cases of uterine hæmorrhage occurring during a febrile disease take place at or near the proper menstrual period, the circumstances being favourable to an excessive loss of blood. In considering what conditions are favourable to the development of menorrhagia or metrorrhagia during such an attack, we should remember that in the early stages of fever we have a quickened pulse with increased arterial tension. Incidentally, I may remark that in normal menstruation we have increased arterial pressure with slight pyrexia. In the uterus we have an organ with an unusually good blood supply, and, moreover, it is the only organ in the body from which blood escapes normally as a physiological process. With an increased vascular tension, it is only what we might then expect for blood to escape more freely from the mucous membrane, which probably feels and is most influenced by the increase of arterial pressure. A yet stronger factor, however, is probably at work in the causation of hæmorrhage in the febrile state, and it is *the alteration in the character of the blood.* What these alterations consist of we know as yet little or nothing; but whilst it has been said that in some fevers there is an increase in the fibrin-forming constituents of the blood, undoubtedly in others there is a deficiency in these elements, and consequently a marked fluidity and want of coagulability is observed. I believe this to be the case in many of the zymotic fevers.

That the want of the properties of coagulation in uterine hæmorrhage is not explained by its being menstrual blood, and due possibly to the action of the acidity of the vaginal mucus, is proved by the fact that blood coming from the intestinal mucous membrane, or which has been abstracted by the operation of venesection, has the same characters. Trousseau, when speaking of intestinal hæmorrhage during enteric fevers, says,[1] "At the necropsy of persons who have died of enteric fever, we often find bare mesenteric vessels at the bottom of the intestinal ulcerations. Hence it might be supposed that these hæmorrhages are attributable to the rupture of a mesenteric vessel during the process by which

[1] Clinical Medicine, vol. ii., p. 332.

Digitized by Google

the furuncular core is eliminated. Still, for the most part, if not always, this is not what occurs. Blood is exuded by the mucous surface exactly as it is in hæmatemesis and epistaxis, as well as in many other similar circumstances. The immediate cause of this sanguineous exhalation is an essential change in the blood, which is in a dissolved state—a fact you can verify by examining the blood abstracted from patients in our hospital wards.....This particular condition of the blood is seen in a very high degree in the hæmorrhagic putrid fever, and in yellow fever. In scarlatina, diphtheria, measles, and small-pox the blood is also generally in this dissolved state, and to it are attributable the intestinal, renal, and nasal hæmorrhages met with in them. So far is ulceration of the intestine from being a condition essential to the production of hæmorrhages, that they often come on at a period of the disease very far removed from that to which ulceration belongs."

The difficulty and sometimes impossibility of stopping bleeding in fevers was frequently experienced in the days when venesection and the application of leeches were much resorted to in their treatment. Only three years ago I was called into consultation with a practitioner of the old school, who, having applied ten leeches to the chest of a child suffering from pneumonia, produced hæmorrhage which was quite uncontrollable, and proved fatal. In these changes of the normal characters of the blood, together with the increased arterial tension, lies the explanation of the profuse menstrual discharge, or the occurrence of hæmorrhage apart from menstruation, during a febrile attack. If the normal menstruation has not taken place recently, and should it not appear during the earlier stages of the fever, in all probability it will not take place during the after progress or convalescence of the disease; and if it should, the arterial pressure being then lessened, the loss of blood may be diminished rather than increased; but occasionally uterine hæmorrhage, either as menorrhagia or metrorrhagia, does appear as a sequel to fevers, when we may consider it as probably due to the changes in the blood alone.

I shall now briefly relate particulars of two cases of menorrhagia which occurred respectively during typhoid fever and small-pox, and which, I may add, are the only two cases I have witnessed requiring treatment.

In October, 1884, I was called to attend a lady, aged forty, the mother of five children, who had been particularly strong and healthy. She had been at a picnic eight days before, when she got her feet very wet. She had since had a good deal of shivering, and for three days previously had suffered with severe neuralgia, for which I was consulted. I found her pulse very quick, and was convinced that the neuralgia was only a symptom. It was evening, and the temperature was 105°. There was a slight pleuritic rub heard on the left side, and pain was complained of; the abdomen was somewhat distended and tender, and there were some ill-defined lenticular spots of a rose colour, but no diarrhœa. Next day the bowels were very loose, the stools being of a pea-soupy character. The morning temperature was 104·6°, and the evening 104·8°. I diagnosed the case to be enteric fever. Three days afterwards I was informed that menstruation had taken place. I had been consulted by this lady two months before with reference to the menstrual loss being more than usual; and finding great regularity had persisted for five years, since her last child was born, and no history of miscarriage, whilst other symptoms were complained of, I considered the hæmorrhage due to the menopause. The following day (being, as far as I could judge, the twelfth day of the disease) the morning and evening temperature were nearly alike; the diarrhœa had ceased, but I learned that the discharge of blood was considerable. There was low muttering delirium almost constantly. Next morning, finding the patient considerably weaker, I became anxious about the loss of blood; and, seeing the enormous quantity of dark liquid blood which, according to my orders, had been saved, having been wrung out of the diapers, I determined to administer hæmostatics. Full doses of ergot and gallic acid were given at frequent intervals, also champagne and nourishment. My evening visit found the patient's temperature slightly lower, the pulse greatly softened, but the hæmorrhage quite as free. I was anxious for someone to share the responsibility of the case with me, and at the friends' wish I asked Dr. Gibb to consult with me. Next morning, finding the usual hæmostatic measures of no avail, tincture of digitalis was given every three hours, cold applications were applied to the vagina, and I remained with my patient most of the day. Eventually I was compelled to plug the vagina, after which no hæmorrhage ensued. My patient, however, sunk into a collapsed state; a clammy sweat covered the body, which was cold. I stayed with her the whole night, and, by applying warm bottles and bricks around the body, and administering stimulants and food very freely and frequently, the temperature was recovered. A good reaction taking place, and no recurrence of hæmorrhage, she gradually improved, and, with the best of skilled nursing, made a good recovery. I should scarcely like to estimate the amount of blood lost, but it consisted of several pints of a dark liquid blood, which did not coagulate. The difficulty in this case was, in the first place, to know when to take active measures to stop the hæmorrhage; and, secondly, to find remedies to accomplish this, for all save that of plugging seemed useless.

The only other severe case I have met with was that of a woman, the wife of a respectable tradesman, who had small-pox. She was at the time suckling an infant. On seeing the nature of the disease, I ordered her to cease doing so. Four days afterwards menstruation, which had been absent during lactation, came on. The patient was a strong woman and in robust health when seized with illness, and the small-pox was confluent in type. I was not particularly anxious about the menstrual loss, and, learning that it was not excessive, I did not interfere. I unfortunately could not get a trained nurse, and had to put up with a particularly bad one of the charwoman type, who evidently considered self-protection was the first object to be attained—the means adopted being to saturate herself with whisky. I was misled by this woman as to the quantity of blood actually lost. At my next visit the patient showed signs of anæmia in the mucous membranes, and the pulse was greatly weakened. I discovered the loss was very considerable, and though active remedies were adopted she died. It is probable that if active measures had been taken to stop the hæmorrhage sooner—which, unfortunately, was of a far greater extent than was anticipated—the result might have been different.

As regards the management of such cases of menorrhagia or metrorrhagia, in many instances, as I have already stated, we may consider the loss of blood, if moderate, as beneficial, and we are right in not interfering with it. The uterine mucous membrane may be considered to be acting as a safety valve, and good effects may possibly result by lowering the blood-pressure and the temperature. But we must be very watchful and cautious not to let the hæmorrhage continue too long lest it become almost uncontrollable. I am convinced that we take too little notice of the occurrence of menstruation during a febrile attack. We may or we may not be casually told that our patient is menstruating, and if we are we treat the remark almost with indifference. In other cases we may not hear of it, the nurse or friends of the patient considering it a natural occurrence and of little consequence. I imagine that in the old days of bloodletting our fathers were accustomed to inquire and take into consideration more than we do the loss of blood by menstruation, for the simple reason that a lowering of the blood-pressure was a part of the treatment in all febrile diseases; and it is, I think, probable that nature's loss frequently saved the operation of venesection. In considering how far the hæmorrhage is beneficial in such cases, we should be greatly guided by the general bodily condition of our patient. We should consider what loss of blood she is capable of sustaining, and be careful to ascertain the former performance of the uterine function, and also learn if our patient is of a hæmorrhagic diathesis. When we have decided that the loss of blood must be checked or stopped, it is not always easily accomplished; the marked fluidity and want of coagulability of the blood in some cases rendering ordinary hæmostatics almost inert, our treatment then must be very active, and, if necessary, plugging of the vagina must be resorted to.

In conclusion, let me suggest that, as careful practitioners, more attention be paid by us to the occurrence of menstruation during a febrile attack; and let us ascertain whether we have menstruation or uterine hæmorrhage to deal with, bearing in mind that the former is a common term for all forms of uterine hæmorrhage with the laity. It is just possible that by an oversight of this kind we may find, too late perhaps, that a physiological process has stolen a march upon us and insidiously become converted into a pathological and maybe a therapeutical difficulty, and that a hæmorrhage which, had it occurred from the nose, lung, stomach, or bowel, would have received every attention at

Digitized by Google

our hands, because it has arisen from an organ which periodically bleeds has been deemed unimportant, and not calling for special attention. It may occasionally happen that in such a neglect lies the explanation of the tardy convalescence or fatal termination of some cases which otherwise seem difficult to understand.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF COUPLE RHYTHM OF THE HEART.

By W. J. COLLINS, M.D., M.S., B.Sc. LOND., F.R.C.S. ENG.

"COUPLE RHYTHM" was the name first given by Dr. Hyde Salter in 1871 to a rare and curious abnormality of the rhythm of the heart beat which he had observed in three cases. The subject did not appear to attract the attention of any observer until 1882, when Dr. Henry Cook of Bombay published three cases he had observed in India, and added a sphygmographic tracing. Recent medical treatises and dictionaries of medicine do not contain any account of this curious phenomenon; and as the cases are very rare, it may be interesting to publish the notes of one that I have had under my observation. Before doing so I may say that the peculiarity consists in the cardiac systoles going in pairs or couples, the pause between the two being much less than that which separates one couple from another. It is not a reduplication of both sounds, as is proved by the pulse, the sequence of events being lubb-dup, lubb-dup, pause, lubb-dup, lubb-dup, pause. It is neither an intermittence nor an irregularity, as Dr. Hyde Salter pointed out. It is rather an intermittent irregularity than a regular intermittence, and the irregularity is singularly regular. All three of Dr. Salter's cases had valvular disease of the heart, so had two of Dr. Cook's cases, while the other was suffering from malarial fever.

J. R——, aged nineteen, a footman, was first seen by me in January, 1882. He complained of palpitation, which became distressing upon exertion, and was getting worse every year; it had troubled him altogether about five years. He had never had rheumatism, had had measles and whooping-cough, with subsequent bronchitis, at three years old, but since then had enjoyed fair health. The apex beat was in the normal situation, the cardiac dulness not increased; on auscultation, what first of all sounded like reduplication of both sounds was heard, but on listening more cautiously, the couple rhythm described above was very distinctly audible. The pulse, too, exhibited the usual anomaly in these cases. The rate was 48 per minute, and the radial pulse synchronised with the first of each couple. On coughing or exerting himself—e.g., lifting a chair,—the pulse rate was immediately doubled, the second systole of each couple being then also appreciable at the wrist, giving 96 pulsations per minute. A sphygmographic tracing gave an ocular demonstration of the anomaly, exhibiting the paired rhythm of the pulse, and the first of each pair being a more powerful systole than the second. There was a short systolic bruit, most distinct at the left base, and presumed to be hæmic in character and causation. It was very remarkable to observe the pulse while the transition from the rapid rate to the exact half of that rate took place; every alternate beat weakened down, until at last it was no longer appreciable to the finger, and sank into the pause. Urine: specific gravity 1026, acid, no albumen. No other physical signs or symptoms beyond considerable anæmia were observed.

I saw the patient once or twice again in 1882, and each time observed precisely the same phenomena. Then I lost sight of him until April, 1885, when he came complaining of a severe cough which he had had two months, with occasional hæmoptysis; and at the right apex were observed increased vocal vibrations and crackling crepitation, while at the left apex were coarse breath sounds. The couple rhythm was still present, but less marked than formerly—that is to say, the pause between the members of a couple approximated to that between two couples. As an opportunity to go to Australia presented itself, he left England in August, 1885. I heard from him in December last from Lithgow (New South Wales). Alas! the voyage had apparently aggravated his lung trouble, and he entered Sydney Hospital on landing with both lungs seriously diseased. Quite recently I have been informed of his death.

In the absence of any better explanation of this rare and striking phenomenon I would suggest as its cause a rhythmic rise and fall in the activity of the medullary cardio-inhibitory centre, akin to the rhythm which we know to exist in the respiratory and vaso-motor centre; this would produce an alternate reining up and relaxation of the heart's spontaneity, and so occasion the symptom described.

ON THE TREATMENT OF HYDATIDS.

By ARTHUR SENNETT, M.D. ABERD., &c.,
FORMERLY HOUSE-SURGEON, LONDON HOSPITAL.

IN THE LANCET of Jan. 15th, 1887, Mr. Laurence Humphry describes a case of hydatid cyst of the liver, in which collapse and an urticarial eruption followed as the result of puncture with a hypodermic needle, and which was afterwards cured by evacuating the cyst. I believe this method is generally adopted, the aspirator or trocar and cannula being used, and the cyst completely emptied. In this country, where the disease prevails, such is the general practice; and I have operated on about a hundred cases in this manner, with a fair percentage of recoveries. My notes do not extend over all the cases, but about ten deaths out of the hundred would be nearly, if not exactly, correct. The conclusion, however, has been forced upon me that this treatment is not the best, and during the last year I have treated each case by puncturing, using a large hypodermic syringe with two needles, drawing off about two drachms of the fluid, and then injecting a similar quantity of a weak solution (two grains to the pint) of perchloride of mercury. The result of each case has been satisfactory; no suppuration has resulted, and the cyst has gradually contracted. The generally accepted principle that collections of fluid in the internal parts of the body should not be suddenly evacuated is thus not violated. The action of the perchloride, even in such minute quantities, is sufficient to destroy the vitality of the echinococcus, which is never great, and the spontaneous method of cure is simulated as nearly as possible. That many cases do get well spontaneously is shown by the fact that in fully one-third of the necropsies I have made at the Hamilton Hospital on men who have lived in the bush for a length of time, and who have been accustomed to drink any water that they might meet with, a shrunken cyst has been found. I am not aware if the above method of treating this disease has been previously described, nor have I opportunities of referring to the literature of the subject. It seems to me to meet the indications and to be based on scientific principles.

FRACTURE OF ASTRAGALUS; SUBSEQUENT NECROSIS; REMOVAL OF CARIOUS BONE; RECOVERY.

By ARTHUR E. SALTER, M.B.

ON August 3rd, 1886, I attended a child (S. C——), aged four years and four months, with an injury to her left ankle joint, caused by her falling from the top of a heap of house studs, some of the timber falling on the ankle. When I saw her she was in great pain, the accident only having just happened. There was no bruising, but the foot was displaced a little outwards, and there was a large effusion of blood beneath the skin on the inside. She was in intense pain. Having chloroformed her and examined the joint, there was crepitation distinctly below the joint, the inner malleolus was broken. Believing the fragments would unite well, I put up the limb in a splint, guarding against pressure over the effused blood, and in this way it was left for a few days, at the end of which, as great pain was complained of, the splint was removed. The limb having been again put up, it was left for three weeks, when a plaster splint was applied and kept on for another three weeks, after which, the pain commencing to be great, the splint was removed, whereupon some signs of approaching suppuration were visible. In this position it was left without any splint, and on

Digitized by Google

Sept. 29th an abscess below the inner malleolus was opened under chloroform, and pus evacuated; on this occasion the opening made with the knife was probed and dead bone distinctly felt. The child took chloroform very badly, requiring a large quantity to produce anæsthesia, and soon regaining her sensation if not kept very deeply under the influence of the drug. On Oct. 4th, under the influence of chloroform, the opening into the diseased bone was enlarged, a small scoop introduced, and a considerable quantity of carious bone in a softened state removed, the cavity so made being well syringed with carbolic water (1 in 80). The bone was still disinclined to heal, and on Oct. 31st the cavity in the astragalus was again scooped out, and more bone in a disintegrated and decomposed state removed. From this date onwards the joint proceeded well. Subsequently a piece of the internal malleolus came away, and the patient was able to walk about, having as a result some enlargement of the joint and not good mobility. I believe the mobility will considerably improve as time goes on, the patient being so young.

Thursday Island, Queensland.

PUERPERAL PYREXIA.

By R. J. CALLENDER, M.R.C.S., L.R.C.P.L.

THE following case may prove interesting and useful to some of the readers of THE LANCET:—

Mrs. P—— was safely delivered of a female child on March 26th. The placenta came readily away and firm contraction of the uterus ensued.—March 27th: Feels quite well. Has taken a quantity of food (slop diet). Discharge abundant.—29th: Slight headache, which she attributes to not having had her bowels relieved since her confinement. Ordered castor oil.—31st: Called at 8 A.M. to see the patient. She complains of excessive heat, restlessness, headache, and thirst. Temperature 103°; pulse 130. Lochia very scanty. Slight pain in the abdomen on the left side. Slight soreness of throat. Ascertained that her bowels had been moved four times. Had been out of bed on the 29th and 30th, while bed was made, and had complained of shivering. Did not sleep the preceding night. Ordered turpentine and hot poultices to be applied to the abdomen, and a mixture containing solution of acetate of ammonia and tincture of opium. I went back at 10 P.M. and found her still very restless. She had had no sleep. Temperature 104°; pulse 140. Lochia very scanty, but not offensive. The uterus was washed out with warm water and Condy's fluid.—April 1st: Has had no sleep. Temperature 105°; pulse 140. Lochia almost ceased. Slight tenderness over abdomen. Ordered a draught containing fifteen grains of quinine, with twenty minims of hydrobromic acid. Called two hours later. She was then sweating profusely, had noises in the head, and was very deaf. She seemed quite under the influence of the quinine. At 10 P.M. the temperature was 104° and the pulse 120. Ordered a quarter of a grain morphia pill, as patient had had no sleep for three nights.—2nd: Temperature 103·2°; pulse 120. Lochia much more abundant; pain gone. Has slept well. Gave fifteen grains more quinine. At 10 P.M. the temperature was 100·2°, and the pulse 95. She felt much better. Lochia profuse. Better able to take the nourishment ordered (half an ounce of brandy, with yelk of egg, every four hours, and beef-tea).—3rd: Temperature 99·1°; pulse 90. Patient has had a good night's rest, and seems inclined to sleep. Ordered a small dose of castor oil. From this time the patient made a good recovery.

I consider the quinine has in this case proved most useful, bringing down the temperature quickly and causing the interrupted lochia to come freely away.

Northumberland.

REMOVAL OF ADENOMA OF THE BREAST: USE OF COCAINE.

By E. F. GRÜN, M.R.C.S.

I DESIRE to give a brief account of the removal of an adenomatous tumour of the breast under the influence of cocaine, no other anæsthetic being used. The tumour, about the size of a walnut, had existed for about six months. The patient, a highly intelligent lady residing at Putney, was extremely anxious for its removal, but had great objection to taking either chloroform or ether. Under these circumstances it was determined to remove the tumour with cocaine only, the ether being at hand in case of necessity. Dr. Woodhouse kindly assisted in the operation, which was conducted in the following manner:—The breast was first smeared with a 5 per cent. solution of oleate of cocaine, which absolutely deadened the pain of the hypodermic needle; then a mixture of a saturated solution of cocaine with the hypodermic injection of morphia (B.P.) was injected over the two extremities of the tumour. In five minutes all sensation had disappeared over an area of about three square inches. An incision about two inches long was now made, the raw surface painted with saturated solution of cocaine, and the tumour gradually dissected out. Two arteries were tied, and the wound stitched together, but it had to be reopened to tie another small artery. The whole operation lasted about an hour and a half. The patient was continually asked during the operation if she felt pain; she stated that she felt no pain whatever. This is the first case in which a tumour of the breast has been removed under the influence of cocaine. The patient has since made a most satisfactory recovery.

Putney.

PUERPERAL ECLAMPSIA; CRANIOTOMY.

By BEAVEN RAKE, M.D. LOND.,
GOVERNMENT MEDICAL OFFICER, TRINIDAD.

ON April 10th, 1887, about 7 P.M., I was called some miles into the country to see B——, a Hindu aged about twenty. I learnt that she had been in labour about twelve hours, and that it was her second child. I found her deeply comatose, lying on her back, her face very sunken, and her pulse 130, very weak. She was said to have been in this state for some hours. The head was at the brim and the os the size of a shilling. There were no pains. I examined the abdomen carefully, but could detect no fœtal movement or heart sounds. Her critical condition seemed to call for immediate emptying of the uterus. After drawing off about half a pint of urine with the catheter, I dilated the os digitally without chloroform, as she was too weak to make any resistance. I then tried to put on the forceps. One blade slipped on easily enough, but the head was so high up that I had not room to get on the second blade. These attempts produced clonic spasms, especially marked in the right upper extremity. Her pulse also became so weak that I feared the result of any more such irritation of the uterus. Feeling also that the child was probably dead, I perforated and completed delivery with the forceps. The child was small, and appeared to be about eight months. There were no further convulsions, and the uterus contracted well. The woman died four days later. She never recovered consciousness.

POPLITEAL ANEURYSM TREATED BY DIGITAL COMPRESSION FOR TWENTY-TWO HOURS; CURE AFTER PREVIOUS FAILURE OF ESMARCH'S BANDAGE AND ELECTROLYSIS BEFORE ADMISSION.

(Under the care of Mr. BRYANT.)

THE first of the following two cases is an example of the value of digital compression of the femoral artery in popliteal aneurysm. The great advantage which it presents over other methods in the majority of instances is so well known, that few surgeons fail to avail themselves of its use when the patient can be treated under conditions favourable to its successful employment. It would be interesting to have fuller details of the methods employed before the patient came under the care of Mr. Bryant. In the second case, it would appear that the prolonged suppuration and

Digitized by Google

inflammation in the antrum was the cause of the new growth which ultimately developed there and required removal. We are indebted for the following notes to Messrs. F. Beard and W. F. A. Clowes.

John E——, aged thirty, was admitted into hospital on Sept. 26th. The family history was good. The patient broke his arm about ten years ago; he has also had yellow fever; with these exceptions he has always enjoyed good health. He first noticed the aneurysm about six months ago; it was a little painful. He does not remember having hurt himself in any way. He has had a great many appliances used, but without success. He had a pad put over his femoral artery, and a weight suspended (partly) over it; finding this did no good, an Esmarch's bandage was tried, but this had no effect. Two needles, attached to an electric battery, were run (across one another) into the aneurysmal sac, and an electric current kept running through; but this had no better effect than the other appliances, so the patient came to the hospital to see if anything could be done for him.

On admission, the patient had a swelling on the outer side of the popliteal space of the left leg, which pulsated, but the pulsation ceased when pressure was applied to the femoral artery.

Sept. 28th.—Mr. Clement Lucas saw the patient this afternoon, and ordered digital pressure to be applied to the femoral artery, and the pressure was commenced at 4 o'clock this afternoon.

29th.—The pressure has been kept up all night, and is still going on (1 P.M.). The swelling, which was before soft and pulsating, has become smaller and hard. The patient had an injection of morphia last night.

30th.—The pressure was discontinued yesterday at 2.30 P.M. No pulsation can be felt in the aneurysm.

Oct. 1st.—There is no pulsation to be felt this morning in the popliteal artery; a slight pulsation can be felt in the posterior tibial artery. The patient's leg is kept still by means of sand-bags, which are placed on either side of the leg. His temperature is normal.

3rd.—There is still no pulsation in the aneurysm, which has decreased in size, but pulsation in the dorsalis pedis can be plainly felt.

16th.—The patient got up for a short time this evening. The aneurysm has become very hard, and has much decreased in size.

31st.—Patient left the hospital to-day; he is quite well. The aneurysmal sac has become very small and hard. The patient has still a little pain round about his knee when walking.

ROUND-CELLED SARCOMA AFTER PROLONGED SUPPURATION OF ANTRUM; PARTIAL EXCISION OF SUPERIOR MAXILLA.

(Under the care of Mr. BRYANT.)

The following notes were taken by Messrs. McDeane and F. J. Nisbet:—

M. H——, aged forty-nine, was admitted into No. 21, Lydia ward, on Feb. 22nd, 1886. Family history good. No previous diseases or injuries. Ten years ago the patient first began to suffer from pains in the head and left side of her nose; then a gathering would form and burst. She got worse about fifteen months ago, and then a swelling came inside her mouth on the upper left jaw; it discoloured her left eye very much. She had some teeth drawn, but this did not help her much. Her doctor then operated, cutting a passage through the left alveolar process into the nose. There was some discharge from the antrum, and this antral suppuration continued for many weeks; it was probably started by the carious teeth above mentioned. She went to the seaside, and returned home quite well. At Christmas she again had pains in her face and eye, and an obstruction of the lacrymal duct, tears escaping over her cheek. She went under an operation on her eye, and was ordered to syringe out her nose with carbolic lotion. About three weeks ago the swelling re-formed in her mouth, and she was advised to come to Guy's Hospital.

On admission the patient was a pale-faced woman; her left cheek was very swollen, and her left eye discoloured and half-closed from œdema of the cellular tissue. Inside her mouth the left upper alveolar process was seen to be greatly swollen. She experienced pain on anything touching her left cheek, the pain shooting up the left side of the face and to the left ear. On looking up the left nostril, a mass of growth could be seen. The left alveolar process showed two or three large polypoid masses, which appeared to be coming from the interior of the antrum. There was a good deal of thickening of the tissues over the left malar bone, and great tenderness on pressure. The mass in the left nostril had much the appearance of an ordinary polypus. There was no depression of the palate or pushing upwards of the orbital plate.

Operation.—Chloroform was administered, and Mr. Bryant commenced by making a vertical incision in the middle line of the upper lip. The coronary artery was twisted, and the incision was carried upwards round the ala of the nose to the left inner canthus. Numerous arteries were twisted. The incision was then carried outwards to the cheek-bone. This flap of skin was then laid outwards, and two vertical cuts were made with a saw through the alveolar process of the superior maxilla (in the middle line and about two inches externally). This piece of bone and tissue was then removed, and the cavity was well scraped and washed out with iodine lotion. The cautery was used to stop any hæmorrhage. The mouth was then washed out with chloride of zinc, the pieces of skin were brought into their proper places and stitched, and the wound dressed with iodoform gauze. The patient's temperature on the night of the operation was 98°.

Report by Mr. TARGETT, *Surgical Registrar.*—The mass of growth removed was rather cubical in shape; there was a large opening in the left gum, circular, one inch in diameter, and leading directly into the antral cavity; this, no doubt, is the remains of the old puncture of the antrum. Through this opening there are large polypoid masses of growth, fungating which are extensions from similar material in the antral cavity. Almost the whole of the thin anterior wall of the antrum has been destroyed, and the growth is now involving the deeper portions of the cellular tissue of the cheek. The antral cavity is quite full of growth, which readily breaks up into pieces; one portion had extended into the left nasal cavity. The line of excision has not gone clear of the growth along the malar border, but the cavity was well scraped at the time of the operation. The growth itself is of a greyish colour, soft, pulpy, and vascular, having the appearance of a soft round-celled sarcoma of the antrum. Under the microscope, masses of round cells, with no fibrous stroma, and large thin-walled vessels, were seen.

Report continued by Ward Clerk.—March 4th: The stitches were all taken out; the sponge came away yesterday evening; patient progresses favourably; the wound looks well and heals nicely.—11th: One or two sloughs come away daily from the inside of the mouth. The wound below the eye is now doing better, the œdema having now almost entirely disappeared. No discharge worth speaking of. Patient doing fairly well.—20th: Patient left the hospital to-day, very much improved in health; the wounds are nearly healed; the cavity at the back of mouth looks healthy; plenty of granulation around the surface.

VICTORIA HOSPITAL FOR CHILDREN.

TRAUMATIC STRICTURE IN A CHILD AGED THREE YEARS.

(Under the care of Mr. H. H. CLUTTON.)

FOR the following notes we are indebted to Dr. Moline, the medical registrar. The case is of interest from the age of the patient, as the child was under two years of age when the symptoms of stricture were first noticed.

A boy, aged three, was admitted in August, 1886, with the following history. When one year and seven months old he was run over by an omnibus, his mother stating that "the horse trod on him and the wheel passed over his leg." For two days his urine was bloody and blood dripped from the end of the penis after micturition. After this the symptoms were those of difficult and frequent micturition, which gradually increased in severity till his admission into the hospital. He was then constantly screaming, straining, and passing only a few drops of urine at a time. The rectum was also frequently protruded. There was no external sign of any injury.

On Aug. 26th, under chloroform, Mr. Clutton succeeded, after injecting the urethra with oil, in passing a fine catgut bougie through a stricture at the bulb. Nos. 2 and 3 silver catheters were then passed, but were very tightly held by the stricture. The patient was much relieved, passed his urine in a stream, and evidently had much less frequent desire to empty his bladder. On Sept. 9th, under chloroform, No. 2 straight silver catheter was passed, and then, in succession, Nos. 3, 4, 5, 6, and 8. They were each in turn tightly held

Digitized by Google

by the stricture. After this operation all symptoms of an irritable bladder entirely disappeared, and he was from this time perfectly relieved. On Sept. 15th straight silver catheters were again passed to ensure the perfect dilatation of the stricture. As Nos. 6 and 7 were not held tightly, still larger sizes were tried, and it was then found that Nos. 9 and 10 could be passed, but the latter was very tightly embraced by the stricture. He suffered in no way from this operation, and left the hospital on Sept. 22nd.

Remarks.—The rupture of the urethra was probably not complete, or the symptoms would have been more urgent after the accident. There was no evidence forthcoming as to the possibility of a fractured pelvis, but it would appear as if the rupture had been produced by direct external violence. Another interesting point is the size to which dilatation of the urethra was carried. The penis was of quite the normal proportions for a child of this age, and yet it readily admitted a catheter of the size of No. 10 English scale. This was done for the purpose of thoroughly stretching the stricture, but it proves that a small lithotrite and evacuating tube could be introduced at this early age if lithotrity were necessary.

BRISTOL ROYAL INFIRMARY.

THREE CASES OF INTUBATION OF THE LARYNX.

(Under the care of Drs. SHINGLETON SMITH and WALDO.)

FOR the following account we are indebted to Mr. James Swain, house-physician.

CASE 1.—E. W——, aged two years and four months, was admitted on April 16th, under Dr. Shingleton Smith. There was marked dyspnœa, as shown by the recession of the epigastrium and supra-clavicular fossa during inspiration; the lips were rather blue, and there was a harsh croupy cough. The fauces generally were red, and the tonsils slightly swollen. Temperature 100·6°. By three hours after admission the dyspnœa had become so urgent that intubation (after O'Dwyer's method) was performed. This was followed by a slight attack of coughing, which lasted about half a minute, and then the child breathed quite calmly, the relief being perfect. Throughout April 17th the patient continued comfortable, the temperature ranging between 100° and 102·8°. The slight cough, which still continued, was almost aphonic. — 18th: Tube removed, after remaining in position about thirty-seven hours. After removal, in consequence of gradually increasing dyspnœa, the tube was again inserted about three hours after removal. This time, however, it remained in only for a few minutes, being ejected during a violent attack of coughing. From this time the child improved, the temperature gradually lowering until it became normal on April 23rd. The voice continued to be rather hoarse for upwards of a week after the removal of the tube. A slight attack of broncho-pneumonia supervened, but this did not appear to be in any way connected with the process of intubation.

CASE 2.—R. B——, aged five years, was admitted on April 24th, under the care of Dr. Waldo. The mother stated that the child had been ill a week with symptoms of catarrh, a cough of harsh character, and gradually increasing dyspnœa, with occasional attacks of greater severity but comparatively short duration. On admission, the child's face had a leaden hue; there was great restlessness and dyspnœa, although little epigastric recession; cough of croupy character; fauces slightly reddened, but no membrane visible. Urine concentrated, and containing a trace of albumen. Temperature 101·2°. The symptoms of dyspnœa gradually increased, although temporary relief was obtained by the action of an emetic powder, and intubation was resorted to during a severe attack of paroxysmally augmented dyspnœa early in the morning of the 25th. This was followed by marked relief, but not so complete as in the foregoing case.—April 26th: Cough rather severe. Child is able to speak, but the voice is not loud. Urine still albuminous. In the evening, about thirty-six hours after its introduction, the tube was expelled during a severe attack of coughing. Two hours after the ejection of the tube the child coughed out a piece of false membrane about three-quarters of an inch long. The temperature ascended to 104°, but in all other respects the patient seemed better. A gradual improvement took place, and the temperature reached the normal line on April 30th. On May 1st, however, an increase in the amount of albumen in the urine occurred, and the temperature rose to 102°. It continued elevated for a few days, and then the child began to convalesce. The albuminuria disappeared finally on May 5th. The child's voice was hoarse up to the time of her discharge from the infirmary on May 13th.

CASE 3.—J. M——, aged three, was admitted on May 10th, under the care of Dr. Smith. The patient had only been ill one day with cough and difficulty in respiration. On admission no abnormal appearance about the fauces, but croupy cough and slight dyspnœa. Temperature 99°; urine acid; no albumen.—April 11th: Dyspnœa getting worse, but was slightly relieved by emetic powder.—12th: Patient has had several paroxysmal attacks of dyspnœa during the night. The face is livid, and there is marked epigastric recession. The administration of an emetic powder caused no diminution in the symptoms. Very little air is now entering the chest. The pulse is small and feeble, and the child seems exhausted. Intubation was performed at 6.15 P.M., and was followed by instant relief.—13th: The child continued perfectly comfortable until 5 A.M., when it was found that the string by which the tube had been fastened to the cheek had been gnawed through and the end attached to the tube had disappeared. As the tube was not found *in situ* and had not been ejected, it was concluded that it had been dislodged during the act of coughing and had been swallowed. By 9 A.M. the patient had again become so dyspnœic that intubation with a larger tube was performed; this, however, was ejected in three-quarters of an hour. The breathing continued fairly easy for a few hours, and then the child again became dyspnœic. Temperature 99·4°.—April 14th: Intubated again at 12.30 A.M. Again followed by instant relief. Rhonchus over lungs behind. Slight diarrhœa. Temperature ranging between 99·8° and 102°.—April 15th: The child seems rapidly getting weaker. Pulse 172; respiration 44; temperature gradually ascending, 103° at noon. Air seems to enter the chest fairly freely; no moist sounds; rhonchus over back of the lungs occasionally. Death occurred at 4 P.M., the temperature in the groin being 106·4° just before death, and 109·4° in the rectum immediately after. At the necropsy the trachea and bronchi showed marked signs of acute inflammation, a slight amount of frothy fluid could be squeezed out of each lung, there were a few patches of pulmonary collapse, and emphysema was markedly present in the right and slightly so in the left lung. The tube which the child had swallowed was found in the cæcum, to which it had travelled without doing any apparent injury.

Remarks by Drs. SMITH and WALDO.—The subject of laryngeal intubation has been more or less freely discussed in recent medical publications, but in England, at all events, this comparatively new operation is now on its probation, and cases thereof have been sufficiently few to justify us in pointing out any practical lesson which has been gained from the above cases without any attempt at theoretical speculation as to the merits or demerits of the operation in general. In introducing the tube, it seems best to have the child sitting on the nurse's lap with the head slightly inclined forwards towards the sternum. The tip of the finger which is passed into the child's mouth, after passing over and hooking up the epiglottis, nearly always impinges on the top of the arytenoid cartilages, and the tube, when introduced, can be felt in front of one's finger passed into the lower part of the pharynx behind the upper opening of the larynx. From want of familiarity with the operation, we deemed it advisable in the above cases (except the last intubation of Case 3) to fasten the string which is attached to the tube during its introduction to the cheek of the child by means of strapping. This is, we are convinced, a mistake, for it irritates the child, and by the movements of the tongue under the string the tube is apt to be dislodged, because the outer end, which is fastened, is necessarily a fixed point. The tendency of the tube seems rather to be ejected from than to be drawn into the larynx, and Case 3 shows how the tube may be dislodged and swallowed in spite of an attempt to secure the tube. The process of removal of the tube is, moreover, a comparatively easy one. The acute tracheitis and bronchitis which occurred in Case 3 we feel almost bound to attribute directly to the operation; for the intensity of the inflammation was greatest in the upper part of the trachea and diminished as it went down the respiratory tract. Whether the insertion of a tube which was presumably rather large (for the child had swallowed the tube which corresponded to the size of its larynx) had an increased effect in the causation of this

Digitized by Google

inflammation we cannot say, but no doubt there is a tendency to the occurrence of laryngitis, as indicated by the hoarseness of voice which persisted in the other cases some time after the removal of the tube. It is, perhaps, interesting to note that the tube which passed so harmlessly through the pylorus and ileo-cæcal valve measured two inches in length. We cannot enter upon the question of the relative value of tracheotomy and intubation, but it is right to state that in each of the above cases we should have been absolutely compelled to perform tracheotomy had not the process of intubation been substituted. Our object is rather to show that intubation of the larynx is in some cases attended with perfectly satisfactory results, but yet has dangers of a somewhat more serious character than some recent writers would lead us to suppose.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Dermatitis Gangrenosa Infantum.—A form of Inflammation of the Lips and Mouth, usually attended by some Disease of the Skin.

THE last ordinary meeting of the session of this Society was held on Tuesday last, Mr. G. D. Pollock, F.R.C.S., President, in the chair.

It was unanimously agreed, on the proposal of Sir DYCE DUCKWORTH, seconded by Dr. CRAWFORD, that an address be presented from the Society to Her Majesty the Queen on the occasion of the completion of the fiftieth year of her reign.

Dr. RADCLIFFE CROCKER read a paper on Dermatitis Gangrenosa Infantum. Four groups of cases were described. In the first there was no evidence of varicella antecedent to the gangrenous or ulcerating eruptions, and in most it was distinctly negatived. In the second group are cases in which varicella has preceded the sloughs or ulcers, which either developed immediately upon the varicella pustule or occurred as a sequela beginning in independent lesions. In the third group vaccination was the immediate antecedent. In the fourth group are placed certain cases of local gangrene resembling cancrum oris; but the individual lesions began in exactly the same way as the independent eruption which followed varicella, and there was a tendency to generalisation, or, at all events, to extension beyond the region in which it started in some of the cases. A general account of the disease was drawn up from an analysis of the preceding and other cases, and it was shown that there is great difference in the severity of the eruption. In some the gangrenous patches were so numerous and extensive as to lead to the death of the patient in a few days, while at the other end of the chain are cases of so mild a character that there were only superficially ulcerating pustules, which came out in crops, thus protracting the disease as a whole for a considerable time, and generally accompanied by intense pruritus; these milder cases appear to correspond with Mr. Hutchinson's varicella prurigo. Between the two extremes are cases of all grades of severity. Comparison was made between the local and general gangrenous eruptions, and, among other things in common, it was shown that they both attack girls more than boys, and occur at about the same ages. The conclusions arrived at were—that the gangrenous eruptions are pathological accidents, so to speak, which in young children, especially when of tubercular constitution, might supervene upon any pustular eruption, although no doubt such a condition is much more common after varicella. Secondly, that the determining factor is probably a micro-organism derived from without, though cultivation and inoculation experiments could alone prove the truth of this theory. Thirdly, that the initial lesions, both of the local and general gangrenous eruptions, present the same characters.—Mr. JONATHAN HUTCHINSON said that he never doubted that other eruptions than vaccinia and varicella could be followed by gangrenous changes. The various specific animal poisons had the power of altering the condition of the patient and rendering him liable to gangrene of the skin and other parts. He had seen many cases of cancrum oris in children who were in excellent health till the measles or other specific fever had overtaken them. There were cases also in which no known antecedent cause could be made out—neither syphilis, nor scarlet fever, nor vaccinia or varicella, &c. He distrusted the view that tuberculosis as a constitutional tendency was liable to set up gangrene of the skin. He thought this was very highly improbable. He thought that we must receive with caution the statement that no evidence existed of the previous occurrence of varicella, for it may be easily overlooked, having occurred in a sporadic form. Infection may occur in individual pustules which are not of varicellar origin; these are not extensive and not symmetrical, but irregular in distribution, and resulting from injury are succeeded by the formation of pus and absorption of the same. He congratulated Dr. Crocker heartily on the value of his paper.—Dr. RADCLIFFE CROCKER was glad to find that Mr. Hutchinson did not differ so very much from the position assumed in his paper. In one case at least the evidence was of the strongest character that the vesicular eruption was not of varicellar nature, and yet gangrene supervened. As to tuberculosis, if well marked and attended with high fever, he thought that it offered a genuine predisposition to the development of gangrene.

Mr. JONATHAN HUTCHINSON contributed a paper on a form of Inflammation of the Lips and Mouth, which sometimes ends fatally, and is usually attended by some disease of the skin. The paper contains the description of a disease (not, it is believed, previously recognised) in which superficial ulcerations occur in the lips and in various parts of the mouth, followed sooner or later by some form of skin disease and tending to a fatal termination. The form of skin disease may vary, but the hands and feet are the parts usually affected, and the nails are especially prone to suffer. In some instances the eruption may consist of bullæ which are followed by free papillary outgrowths. The patients attacked are usually in middle life, or in early senile periods. No special antecedents can be alleged as the probable cause of the malady. Unless checked by treatment the disease appears to run its course in about six months, producing death by exhaustion. There seems reason to believe that opium given in repeated doses will cure it, and that there is, at any rate in some cases, no tendency to relapse afterwards. All the best marked cases as yet observed have occurred in males, but in several milder ones the patients were women. Of the most characteristic, two were master tanners, one was a farmer, one a clergyman, and one a gentleman of no occupation. All these resided in the country. Careful inquiry has failed to support the suspicion that the disease might perhaps be due to contagion from animals. Of these five cases, two ended fatally and three in recovery. The patients who died were those first observed, and since the discovery of the signal efficacy of opium no case has ended in death. The observation as to the efficacy of opium was simultaneously made by the President of the Society, Mr. Pollock, and by the author, two different patients being at the same time under their separate treatment and recovering under this drug. Since that every case has yielded, if the dose of opium were sufficiently pushed. In one, however, the disease did not yield quickly and for more than a month seemed likely to end in death. As regards permanency of cure, in one case the patient is known to be quite well four years after his recovery, in another there is reason to believe that such is the fact, and in a third a period of two years has elapsed. In two of the milder cases, occurring in younger patients, the disease has repeatedly relapsed. A great variety of remedies had been tried without benefit before the use of opium was resorted to. In no single case has there appeared to be any tendency to spontaneous improvement. In all the cases the inflammation of the lips and mouth took definite precedence of the skin symptoms, and in some the latter were very slight. It is not known that any case has as yet been obtained amongst the poorer classes of society. The author desired to abstain for the present from expressing any detailed opinion as to the causes or nature of the malady. He would, however, venture to suggest that it is allied to other forms of disturbed health attended by skin disease and occurring in early senile periods, such as certain peculiar varieties of psoriasis, pemphigus, lichen planus, and pityriasis rubra. In confirmation of this suggestion, and as an appendix to the paper, a case is narrated (with a portrait in illustration) in which an elderly lady had a kind of spreading eczema-psoriasis of the hands and scalp. She lost her nails and all her hair, and was rapidly failing in health in spite of various measures of treatment, but finally

Digitized by Google

recovered quickly and completely under opium. Her case does not belong to the group described in the paper, because she never at any time had inflammation of the mouth.—Mr. POLLOCK referred to the value of opium in all cases of ulceration of the skin. In cases of phagedæna occurring many years ago opium, in his hands, had proved of singular value. He never used any kind of caustic. We were very much indebted to Mr. Hutchinson for the interesting clinical grouping of cases brought forward in the paper.—Mr. MACNAMARA referred to the case which had been under his care. There was no apparent reason for the ulceration and inflammation of the mouth which supervened on the sufferer's return home from India. The spleen and liver were somewhat enlarged. Emaciation and cachexia were already advanced, and although opium was ordered, it was probably not taken as prescribed, and therefore had not had a fair trial.—Dr. RADCLIFFE CROCKER said that so far as the mouth part of the disease was concerned the condition was new to him. He testified to the value of opium in chronic progressive skin affections in old people. Was the affection related in any way to the pemphigus vegetans of Neumann?—Mr. HUTCHINSON, in reply, thought the affection might be so related.

ACADEMY OF MEDICINE IN IRELAND.

Malignant Disease of the Tonsil.—Excision of the Wrist Joint.

AT a meeting of the Surgical Section, held on April 22nd Mr. HENRY GRAY CROLY read a paper on Primary Sarcoma of the Tonsil, and detailed the history of two cases. The first case, Michael D——, aged seventeen years, was admitted into the City of Dublin Hospital on April 22nd, 1886, suffering from a tumour involving the left tonsil and soft palate. The boy was in excellent health until six weeks previous to his admission into the hospital. The disease commenced like ordinary tonsillitis, and so much did the swelling resemble tonsillar abscess that an exploratory incision was made by the medical gentleman who first saw the case; no pus escaped. The patient suffered from dyspnœa and dysphagia. A glandular swelling subsequently formed in the left digastric space. Sir James Paget, who was in Dublin at the time, kindly saw the patient with Mr. Croly, and concurred in his view of the case and in the proposed treatment—viz., preliminary tracheotomy and removal of the growth from within. Tracheotomy was performed on May 4 h. The patient experienced much relief. The tonsillar and palate swelling and the digastric tumour disappeared almost entirely after the bronchotomy, but soon reappeared. Mr. Croly excised the tumour from beneath the angle of the jaw on May 18th, and subsequently removed the tonsillar and palate growth by means of the benzoline cautery. The tonsil and digastric tumours were round-celled sarcoma. The disease returned very rapidly in the digastric space and afterwards in the palate. The patient got drowsy, and suffered from violent headaches; the glands in the neck enlarged. He returned to the country, and died in October—six months from the commencement of the disease. The second case occurred in a man over fifty years of age. The sarcoma was confined to the tonsil, and so much did it simulate tonsillar abscess that an incision was made into the tumour. Mr. Croly declined operative treatment in consequence of extensive infiltration of the cervical glands. The patient returned to the country, and died from exhaustion caused by repeated hæmorrhages.—The PRESIDENT said that the case was one of great clinical interest and of exceptional rarity. Though the operative measure was not attended with success, yet that procedure was eminently justified, and at an earlier stage might have had a different result.—Mr. THOMSON asked whether Mr. Croly had succeeded by this method in getting away the whole of the tonsil with the cautery; because if there was only a spouting mass removed and a portion left behind, the after-history was intelligible. Although he never saw a case of the kind, it occurred to him that the external operation would give increased facility for getting at the structures to eradicate them. The difficulty of operating through the mouth on the tonsil was the uncertainty of removing the whole gland.—Mr. W. THORNLEY STOKER said he approved of the thermo-cautery, and used it freely and frequently; but this was one of the cases in which he would be slow to rely upon it as being an instrument of dangerous facility in finding its way, and therefore if he sought to do more than remove the surface of the gland, especially where malignant disease existed, he would adopt the apparently more heroic operation of dividing the cheek and jaw, and enucleating the gland from its attachment by means of an instrument of less facility.—Mr. KENDAL FRANKS concurred with Mr. Stoker in his objection to the thermo-cautery, not only because the surgeon might travel into undesirable parts, but also because of the increased difficulty which cauterisation created of seeing the limits of the disease. He thought Mr. Croly was right in taking it from the inside, and that the surgeon need not be afraid of going close to the carotid artery, there being a good depth of tissue between the tonsil and that artery to avert danger.—Mr. CROLY replied. His first idea was to relieve the patient by tracheotomy from the sense of choking, having no wish to cut out the tonsil either from inside or outside. His experience of those growths had been, unfortunately, that the operation would only give temporary relief. Hence he asked Sir James Paget what he would do if he had the case in London, and that eminent surgeon replied that he would perform the preliminary tracheotomy and cut out as much of the tumour through the mouth as he could. In fact, in this instance, unless he cut off the boy's head he could not have cut out the disease, and therefore it was immaterial whether he made an external or an internal incision, although he reflected on the hazardous proceeding of cutting within from without. He regarded the case as one of malignant disease occurring with great rapidity, and it was a question whether, in a similar case, he would do anything but tracheotomy to relieve the patient. The external growth was completely encapsuled, and came out as a nut would out of the shell. The wound healed by primary union, but the disease returned with great rapidity, being in the boy's blood. What proved of greatest interest to him was its likeness to tonsillar abscess.

Mr. WHEELER read a paper on Excision of the Wrist Joint.—Mr. HAMILTON asked why Mr. Wheeler retained Esmarch's bandage in this particular excision and objected to it in others. He himself disliked it in almost all excisions, particularly of the knee, owing to the increased amount of blood lost.—The PRESIDENT said there was a tendency to run down Esmarch's bandage, which he was not inclined to endorse from his own experience. In his case, where secondary hæmorrhage ensued, he believed it was due to the faulty application of the bandage, perhaps with too great firmness; but he looked upon it as one of the greatest improvements in modern surgery.—Mr. W. THORNLEY STOKER expressed his unqualified objection to the use of Esmarch's bandage in any excision of a joint; but he would be sorry to object to its use in many other forms of operation—for instance, the removal of necrosed bone, where, without it, the surgeon saw nothing but a pool of blood. In excision of joints, however, there were two great objections to its use: First, troublesome hæmorrhage, which some attributed to want of skill in applying the bandage; but he believed it could never be applied in such a way as to empty the limb of blood without being followed by troublesome hæmorrhage. The second objection was that it altered the appearance of the bone so much that the surgeon could not form a proper estimate as to whether the bone was truly healthy or diseased.—Mr. CORLEY said in excision of the wrist the question of the case being scrofulous was a serious item for consideration, having regard to the probable return of the disease, and therefore the necessity of amputation in the end. Thus Mr. Wheeler's, judging from the ages of the patients, were not strumous cases, and the chances of success were fair. In that view the question of Esmarch's bandage was one of minor importance.—Mr. TOBIN was surprised to hear early passive movement in such cases recommended, except where there was likely to be stiffness. Mr. WHEELER, in reply, said the splint he used was similar to that employed by Lister, but a little more elevated at the heads of the metacarpal bones. Having put in a drainage tube, he bandaged the hand to the splint, putting T nicks at each side, so that he need not remove it. The wrist was steady on the splint, while each finger was moved separately. He had deprecated the use of Esmarch's bandage in excision of joints, for in excision of the knee he had secondary and sometimes intermediary hæmorrhage, and if that occurred whilst the limb was in a fixed apparatus of plaster-of-Paris it would be necessary to take off the plaster-of-Paris to stop the hæmorrhage. He

Digitized by Google

did not, however, condemn Esmarch's bandage in suitable cases where there was considerable oozing, and it was necessary to see the parts; for instance, he used it when removing the cuboid bone. Having used the bandage both ways, with the rubber and elevating the limb, he found that by putting the band round above the seat of operation, and not using the rubber, he had an almost bloodless operation. The best time to begin passive movement was on the second or third day folowing the operation, the metacarpal bone being held steady.

Chronic Interstitial Nephritis.—Ideal Paralysis.—Calculous Pyelitis, followed by Albuminoid Disease.

At a meeting of the Medical Section held on April 29th, Mr. C. H. ROBINSON read a paper on a case of Chronic Interstitial Nephritis, which was published in THE LANCET of June 4th.

Mr. W. BERNARD of Londonderry read a paper on Ideal Paralysis; and another on a case of Neurosis of the Viscera, ending in dilatation of the stomach. He also exhibited macroscopic and microscopic specimens of the latter case.—Mr. CONOLLY NORMAN said the first case detailed in Dr. Bernard's paper exemplified the extreme difficulty attending the diagnosis of apparent physical affections in the insane. Instances of absolute silence for years had also some affinity. He remembered a case recorded in one of the German journals, eight years ago, of a man who had been found wandering in a village and was committed to a lunatic asylum, where he remained for years and never spoke, being silent probably through a delusion, so that his identity was not discovered.—Mr. FITZPATRICK mentioned the case of a girl, aged twenty, admitted into St. Vincent's Asylum, suffering from hysterical mania, and she exhibited delusions assuming a variety of diseases. At one time she fancied her arm was paralysed, and after long persuasion that it was not so she got the use of the arm again. At another time she remained without speaking for months. During these delusions she took her food and gave no trouble to the attendants. At length, in January last, after twenty years of intermittent delusions, she had an attack of epilepsy, followed by paralysis of the right side, and she never spoke from that time to her death. Two months ago she was attacked again with epilepsy, followed by paralysis on the left side. She was then in a state of general paralysis. He never had a second opinion but that there was structural disease in the brain, and his prognosis was verified after twenty years. Dr. Bernard's case would, in all human probability, develop in an attack of disease.—Mr. COX said that he had had himself, in the country, a case of ideal paralysis. A strong healthy man took to his bed, suddenly paralysed, but on examination he came to the conclusion that it was only a case of ideal paralysis; he considered that the man would become paralysed if he remained in bed. His opinion, however, was not accepted. Some time afterwards this man was driving, and the wheel coming off his trap, he was forced to get out, and he walked home.—Mr. MOLONEY asked if there were any history of hereditary insanity or of intemperance in Dr. Bernard's case.—The PRESIDENT doubted whether surgical interference would be useful where the stomach was so enormously dilated, as in the present case, because, even if a fresh pylorus were constructed by the skill of the surgeon, so long as the stomach remained dilated it would form a receptacle for decomposing matters, alimentary and secreted.—Mr. BERNARD replied. In the first case the patient had a motive for lying in bed—namely, to get his friends to pay more attention to him; and his pretending to be paralysed went on so long that really he could not walk. The case had nothing in common with that mentioned by Dr. Fitzpatrick. There was no hereditary tendency to insanity whatever. He regretted not having washed out the stomach twice instead of once in the twenty-four hours. Power was never lost over the rectum and bladder.

Dr. J. W. MOORE read a paper on a case of Calculous Pyelitis, followed by Albuminoid Disease. The patient, a porter, aged seventeen, was admitted into the Meath Hospital, under his care, on Thursday, March 24th, 1887. He was exceedingly ill—wasted, blanched, and weak. On being questioned as to the duration of his illness, he said that his legs began to swell a fortnight previously, when also severe pain in the left groin set in. His appetite was bad. The first touch of the liver suggested the probable existence of albuminoid change in the organ. At the same time it was ascertained that the spleen was certainly not to any extent enlarged. The urine, however, was found to be highly albuminous, showing on microscopical examination a few hyaline tube casts, but no pus-corpuscles or blood-cells; it was acid in reaction, and its specific gravity was only 1010. There was moderate anasarca of the lower extremities, and the left leg was flexed, as in hip-joint disease—vital ankylosis. The patient died on April 16th. At the necropsy, the lungs and heart were found to be practically healthy. The liver was greatly, yet uniformly, enlarged. It weighed 7 lb., was very firm and hard, and yielded a pink colouration with aniline blue. The pancreas and spleen were inseparably welded together by old adhesions; they weighed jointly 13½ oz. The spleen was slightly congested; its capsule was thickened, and presented appearances of former perisplenitis. It showed the characteristics of the "sago spleen" of albuminoid disease. The pancreas was firm, almost cartilaginous, and the neighbouring glands were enlarged. But the interest attaching to the examination attained its climax when the kidneys and their environs were reached. The left kidney, or what remained of it, was embedded in a mass of dense, cartilaginous-looking connective tissue. On cutting through this, the organ itself was found almost entirely destroyed, converted into a multilocular cyst with intervening bands of chondroid connective disease. The cysts contained a horribly fetid urino-purulent fluid, and branching calculi were found in some of them. The pelvis of this kidney was obliterated, as the result of old-standing calculous pyelitis, and the ureter also was thickened and widely dilated down to a point about 2½ inches above its entrance into the bladder, where it was completely occluded by a smooth oval calculus. This was of a bluish-black colour (from deposition upon it of a sulphide), so resembling a piece of limestone rounded by the action of the sea. Passing downwards from the tunica adiposa and invading the sheath of the left psoas muscle, a fetid perinephritic abscess had tunnelled, so causing the pain and stiffness in the left hip joint. The presumption is that during the closing weeks of the patient's life this abscess had partly evacuated itself by the bowel, but a careful examination with a catheter failed to discover any opening—valvular or otherwise—into the intestine. The absence of pus in the urine was satisfactorily explained by the complete occlusion of the left ureter, as above described. The left kidney and its surrounding connective tissue weighed 6 oz; but the right kidney weighed more than twice as much—14½ oz., or between three and four times the normal weight of the viscus. It had evidently undergone compensatory hypertrophy to a very marked extent; but in time its fate also overtook it, and at the moment of death it was the seat of albuminoid disease, only in a less degree to the liver. A histological examination confirmed the widespread existence of albuminoid disease.—The PRESIDENT said the case illustrated the difficulty attending the diagnosis of renal mischief. The quantity of urine passed was an important element in disease of the kidney. The morbid specimen had not the very pale colour and consistency for which the genuine albuminoid liver was distinguished.

CAMBRIDGE MEDICAL SOCIETY.

AT a meeting on April 1st the following communications were made:—

Dislocation of Lens.—Mr. DRIGHTON showed a patient with complete dislocation backwards of the lens of more than twenty years' duration. There was no history of a blow or fall: T = + ?, vision only central; with + 11 D. V = $\frac{2}{3}\frac{0}{0}$. With the ophthalmoscopic mirror the lens could be seen freely movable in the vitreous, and of an opaque bluish-white appearance. Examination of the fundus revealed extensive patches of superficial and complete atrophy of the choroid. The optic disc was cupped. Dust-like opacities were present in the vitreous. Vision in the other eye was $\frac{2}{3}\frac{0}{0}$. The patient had suffered severely from syphilis.

Puerperal Fever.—Mr. WHERRY gave a report of an important outbreak of Puerperal septicæmia in Bedford, Gamlingay, and seven villages around. There were at least twenty deaths occurring in the practices of seven different medical men. The outbreak at Gamlingay was especially mentioned: cases occurred from November, 1884, to August, 1885. There were thirteen cases of fever and nine deaths. There was one case of sudden death. The patient expressed

Digitized by Google

herself as feeling perfectly well, had a good appetite, and went downstairs. Her temperature was never below 103°, nor her pulse under 120. One week after confinement, while partaking of tea in bed, she fell back dead. An incident illustrating the condition of some of the houses in regard to overcrowding and the method of propagation of the poison by the patients and their friends was also related.

Sanitation of the Lying-in Chamber.—Dr. BOXALL, in a paper dealing with the above subject, pointed out that much of the illness following delivery was essentially of a preventable nature. It is not the mortality alone which should be taken into account. Those minor ills of the puerpera, the outcome of less fatal attacks, must be also included. Septic poison can only be produced within the passages where air is permitted to enter, or any decomposable material is left behind; for both the presence of air and a suitable nidus are essential to decomposition. A special liability, however, exists of the poison, ready made so to speak, finding an entrance from without. Dr. Boxall urged the importance of inquiring into the antecedents of the nurse, with a view to ascertain if she had been nursing or otherwise brought into contact with any person suffering from septicæmia or pyæmia, burns, abscesses, or acute specifics. If exposure have occurred, he advised a complete change of clothing, and a general carbolic or iodine bath. He regarded as the most important element in antiseptic midwifery the thorough washing of the hands with soap and water, including the use of the nail-brush; but he further advised the soaking of the hands and wrists in strong antiseptic solution (sublimate 1 in 1000, or carbolic acid 1 in 20) immediately before making any examination, performing any obstetric operation, or touching the genitals of the patient. Second only in importance to this was the thorough washing and subsequent disinfection of all instruments and utensils employed. The abolition of sponges, and the employment of cotton wool or tow in place of napkins, he thought beneficial in every way. Special inquiries should be made into the source of all articles passed on from one patient to another, such as binders and mackintosh sheets. Parish bags in use among the poor should always be regarded as likely to contain assorted samples of infection. The condition of the drains should be carefully ascertained, and any defects remedied long before the expected date of the confinement. Too little attention was frequently paid to this point, and also to the subject of ventilation. A fire should be kept burning in the grate, and one window at least opened a few inches at top. With regard to the choice of antiseptic agents, he urged the advisability of employing one of universal applicability rather than several, more especially when incompatibility exists. Sublimate is incompatible with soap (hence the hands must be well rinsed before they are immersed in the solution) and with oils (hence sublimated glycerine or vaseline should be substituted for carbolic oil or lard, as a lubricant); carbolic acid is incompatible with Condy's fluid, which, again, is decomposed by soap, while iodine enters into combination with the alkali contained in it. These are points which are frequently overlooked. Whatever antiseptic be used, the strength should invariably be measured accurately, for if the proportion be merely guessed at, not only may the solution be so weak that its sepsis-destroying properties become much deteriorated or are quite destroyed, but, on the other hand, it may be so strong that great danger may result, either locally to the living tissues or generally by absorption, especially when the more powerful agents are employed, in the form of douche after delivery. For the hands and instruments he advocated the invariable employment of corrosive sublimate (1 in 1000), or carbolic acid (1 in 20): solutions of the same strength to douche the vagina in every case during the first stage of labour, and after labour subsequently to douche the uterus also, where any intra-uterine interference or foul discharge from the cervix specially indicated such a proceeding. But after the first douche the solution might usually be reduced to half the strength. The sublimate douche frequently administered was not unattended with danger, and he would never advise its use unless the patient were under constant observation. In ordinary cases, when the douche was given as a routine practice, he considered Condy (colour of claret) or boracic acid (saturated solution) of sufficient potency. While he invariably advocated the douche (given morning and evening till the lochial discharge ceases, at from 110° to 115° F.) as a routine practice when the services of a competent nurse are available, he felt sure that in the hands of an ignorant woman more harm than good might ensue. In such a case it was advisable to trust to the more simple details necessary to ensure thorough washing and disinfection of the hands and instruments, the exclusion of all sources of infection and of decomposition from, and free ventilation of, the lying-in chamber, and to limit the employment of the douche to the labour, unless special circumstances dictated its subsequent use, and then it should be performed by the doctor in person or under his immediate supervision. Intra-uterine irrigation should never be entrusted to the nurse, however efficient she may be.—Dr. INGLE thought Dr. Boxall must have selected an unusual season or place for the statistics given. He did not think the experience of private practitioners would furnish anything near such an estimate, but rather evidence wholly to the contrary. Effort after such sanitation as had been described by Dr. Boxall might be of service in lying-in institutions, with trained skill and careful medical oversight; but in general practice he thought it undesirable that much interference with the parturient should be encouraged other than great cleanliness. Injections of vagina, except specially needed, were rather to be discouraged as involving many risks.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

A MEETING was held on April 14th (Mr. W. A. Garrard in the chair), of the proceedings of which the following is an abstract:—

Malignant Tumour of Œsophagus.—Dr. J. D. WYNNE showed an œsophagus which was involved in a cancerous mass for about six inches from just above the root of the lung downwards, greatly reducing the calibre of the tube below. The patient was aged seventy-nine, and for about a year suffered from occasional dysphagia, which became worse during the last three weeks of life, so that eventually all food was rejected. The tumour was a typical scirrhus. It was interesting to note that during life the patient had complained of no symptoms of heart disease, but had a loud mitral systolic murmur, and at the post-mortem the mitral valve was found to be roughened and very much dilated, the left auricle also being greatly dilated and the left ventricle hypertrophied.

Pemphigus Neonatorum.—Mr. JEFFREYS related this case, occurring in a child five days old. It was not specific; bullæ existed on the face, chest, back, abdomen, arms, and legs; confluent, some being as much as three inches in diameter. The case was treated successfully with opiates and arsenic, the body being washed occasionally with bran water and anointed with purified vaseline.—Remarks were made by Mr. Jackson, Dr. Dyson, Dr. S. Roberts, and Dr. Keeling.

Sarcomatous Tumour of Anterior Lip of Uterus, complicating Labour.—Mr. JEFFREYS also related this case. The patient was in her second pregnancy. Barnes' bags were employed and forceps applied. There was considerable hæmorrhage. After the birth of the child the tumour descended to the vulva, and was found to be a rounded mass of about two inches in diameter, attached to the uterus by a thin pedicle. It was removed by transfixing the pedicle, applying a silk ligature, and cutting it off with a pair of scissors. Satisfactory recovery resulted. Dr. Galabin had kindly examined the tumour, and called it a fibro-sarcoma of the cervix uteri. The time elapsed was too brief at present to discuss the question of recurrence of growth.

Dr. W. R. THOMAS related a case of Paralysis of both Arms from severe exertion.

Mr. SNELL introduced a patient with Right Homonymous Hemianopsia.

BIRMINGHAM HOSPITAL SATURDAY FUND.—A meeting of the subcommittee appointed for the purpose of considering a scheme for the distribution of the proceeds of the local Hospital Saturday collection was held at Birmingon the 8th inst. The total sum received up to the present time exceeds £6800—more than £100 in excess of last year's collection. It was decided that £5500 be divided amongst the medical charities of the town, the apportionment to be conducted on the plan adopted in previous years—namely, in proportion to the ordinary current expenditure of each institution, as stated in the last published or audited report.

Reviews and Notices of Books.

Die Allgemeine Pathologie, oder die Lehre von dem Ursachen und dem Wesen der Krankheitsprocesse. Von Dr. EDWIN KLEBS. Erster Theil: Die Krankheitsursachen; Allgemeine Pathologische Aetiologie. (*General Pathology, or the Doctrine of the Causes and Nature of Morbid Processes.* By EDWIN KLEBS. Part I.: Causes of Disease; General Pathological Etiology.) Jena: Gustav Fischer. 1887.

THERE are few writers better qualified to produce a work of the scope indicated in the above title than the well-known Zurich Professor. His name has for many years stood in the foremost rank of scientific pathologists for his abundant original researches and for his admirable "Handbook of Pathological Anatomy," which seems to have been destined, like the classical treatise of Virchow upon Tumours, never to be completed. Nevertheless, it remains as a monument of industry and genius, and, since its appearance, it has been succeeded by other text-books, which may have replaced although they have not surpassed it. We trust, however, that a different fate is in store for the present work, and that it will be speedily completed. Professor Klebs is himself sanguine of being able to publish it all within twelve months, and, if his anticipations are fulfilled, we shall soon be in possession of a treatise that may mark an epoch in the history of pathology. For, as he points out in the preface, the sphere of pathological science has greatly changed. It has no longer to confine itself within the limits of morbid anatomy, but has to determine in what manner the anatomical lesions are brought about. Etiology has become an integral part of pathology, and disorders of function have to be dealt with as thoroughly as those of structure. Cohnheim recognised this extension of the pathological domain, but even he failed to grasp it in its entirety. For in the main Cohnheim's work was limited to the elucidation of disease by reference to normal physiological action, whereas Klebs considers that the external agencies operating to induce disease should also receive full treatment at the hands of the pathologist. It is not enough, he says, to employ pathological research merely to explain the symptoms of disease, nor, on the other hand, simply to detect the various modes in which the diseased organism differs in its action from the healthy. The first is too superficial, and is inadequate to solve many problems of disease; the second is misleading, for it is based on the assumption, too often erroneous, that physiological and morbid processes are similar in their operation. We can thus understand why Professor Klebs was always opposed to accepting the cell doctrine of pathology as a final explanation of disease, and why he was among the earliest to recognise the intervention of micro-organisms in morbid processes. We doubt if full justice has been rendered him in this regard. Though, like many pioneers in other fields, he may have allowed his conceptions to overstep legitimate bounds, yet in the main his contention was true. Day by day we are learning its truth, as we meet with proofs of the origin of disease through parasitic agencies, and note how much of what we term predisposition is the permanent effect upon the individual, and even on the race, of the changes wrought in the organism by previous disease. Cellular pathology by itself is incapable of explaining these things, nor can bacteriology, by itself do so. It is the combination of these two—the struggle between cell life and bacterial life—which enters so largely into our conceptions of disease at the present day, and is destined doubtless to still further developments in the future.

Such are the ideas which appear to have dominated in the mind of the author when he determined to write this book—which he intends should treat of general pathology as a science in itself, without regard to the aims of the therapeutist. He is so purely a pathologist that he almost deplores the practice of medicine, as being more or less a hindrance to the advance of pathology. Yet is it not true that pathology must be worked out on its own lines and its fruits be gathered before they can be utilised in the treatment of disease? Treatment must perforce remain in great measure empirical, for medicine has not yet attained to the certainty of a science. We deceive ourselves when we talk so largely about "rational therapeutics," and there is no shame in acknowledging that treatment is largely based on experience, without any reference at all to pathology. If we may venture to look forward to the future position of practical medicine, we should anticipate that it will be concerned for the most part in efforts to deal with the causes of disease, and that prophylaxis will then be as much a part of therapeutics as symptomatic treatment is at present. Pathology then will hold the field, for it is to that science that we must look for the solution of problems as to the causation as well as the nature of diseases. No longer will the "mere pathologist" be regarded as unpractical; rather he will have the keys of all the science of medicine in his hand, and will reveal to him who seeks the mysteries of disease and the methods for its subdual. If this be so—if, indeed, the medicine of the future is to be based upon the facts of pathological research—we may gladly welcome the attempt to mark the position at which pathology has attained in our day, so as to gather therefrom what hope we may of the near approach of this millennium. Professor Klebs has undertaken to do this, and the first of the three parts into which he has divided his work is that now before us. This volume deals with etiology, the next will treat of pathological morphology (in other words, the structural changes in tissues and organs induced by disease), and the third with pathological physiology (the derangements of function).

The first chapter in the present volume discusses the Nature (*das Wesen*) of Disease, from which it appears that our modern knowledge has not advanced beyond the old conception of an *ens morbi*, the only difference being a substitution in terms. Professor Klebs holds that the varied manifestations of disease depend more upon variations in the nature of the etiological factors than in the morbid process itself; but he is careful to make a distinction between the processes and the conditions or states of disease. The former imply activity, and consist in a series of orderly phenomena connected together in time or seat, and are often referable to one and the same cause; the latter are permanent local changes, material lesions, or functional derangements, such as may be imparted by inheritance or initiated by mechanical causes. He holds that these "morbid states" are to be regarded as disease, although often it may be difficult to mark the point where the permanent lesion passes into the active outbreak of disease. A general disquisition upon Etiology forms the basis of the next chapter, where the operation of external agents, combined or not with internal peculiarities or proclivities, is especially dwelt upon. The doctrine that in many diseases the causes are multiple and not single is one that is apt to be disregarded practically. The internal causes or tendencies to disease, as exhibited by heredity or otherwise, are then dealt with, the subject being illustrated by reference to striking genealogical diagrams of many inherited affections. The light thrown on this subject by Darwinism is fully recognised, and the chapter is a most instructive one. But the main bulk of the volume is concerned with those etiological agencies which more than any other have riveted the attention of the pathological world. These pathogenic organisms have, thanks to the labours of biologists as well as of pathologists, been now so clearly differentiated that their recognition is one of the ordinary processes of pathological inquiry. They are discussed here, however not simply from their morphological

Digitized by Google

side, but with considerable detail in respect to the changes they initiate in the tissues and organs of the body. Professor Klebs brings all his vast experience to bear upon the elucidation of these great questions, and his work will serve to enhance the interest which attaches to the subject; whilst for purposes of reference the book will prove invaluable. There are many coloured plates and illustrations in the text, upon which we would fain dwell longer did space permit.

Photography of Bacteria. By EDGAR M. CROOKSHANK, M.B. London: H. K. Lewis. 1887.

THE application of photography to microscopical investigation has, in spite of its difficulties, made considerable advances of late. That it entails very great advantages cannot be seriously doubted, since it entirely does away with the intervention of the draughtsman in depicting the characters of a microscopical specimen. Desirable as it may be in histology, the adoption of photography in bacteriology is even more to be wished for; and there is no saying how important it may prove in correcting observations and harmonising conflicting statements concerning such minute objects, where the liability to misinterpretation on the part of the observer is enhanced by the conditions under which the observation is made. Mr. Crookshank should therefore be congratulated in his successful attempt to popularise the employment of photography in bacteriological research in the face of discouraging opinions as to its value put forward by high authorities. A study of the numerous reproductions of his photographs which are contained in this work shows both the weakness and the strength of the procedure. Some are as clearly defined as could be wished; others suffer from lack of definition and lose their characteristic features, without, however, any interference with their general grouping. It will be noticed that the "enlargements" of negatives are those which present the least satisfactory characters; but even in spite of the additional difficulties encountered in procuring good impressions of such enlargements, no more successful results could be desired than those representing Proteus Zenkeri (Plate iv., figs. 1 and 2), Bacillus anthracis (v., 2; vi., 1 and 2; viii.), Bacillus tuberculosis (x., 2), Bacillus alvei (xi., 2), Spirillum Finkleri (xiii., 1), Spirillum choleræ asiaticæ (xiii., 2), Spirillum Obermeieri (xiv., 2), Spirillum volutans (xv., 1), and the cover-glass impressions of Bacillus figurans (xvi.). The photographs from which these enlargements were made are all included, so that the reader can compare the results. These plates will form an excellent addition to the descriptions of such text-books as the author's manual of bacteriology. The technical description of the method of photomicrography pursued by the author is so clear and detailed that it will prove of the greatest service, and will, we trust, impart a stimulus to the study of an interesting and useful subject, which there is good hope may do a great deal to impart precision and accuracy to microscopical investigations.

The Diagnosis and Treatment of Diseases of the Kidney amenable to Direct Surgical Interference. By W. BRUCE CLARKE, M.A., M.B.Oxon., F.R.C.S., Assistant Surgeon to, and Senior Demonstrator of Anatomy and Operative Surgery at, St. Bartholomew's Hospital; Surgeon to the West London Hospital. With Illustrations. London: H. K. Lewis. 1886.

THE volume before us is to all intents and purposes the essay to which the Jacksonian prize was awarded in 1886. The fact that it was considered worthy of this reward by the Council of the College of Surgeons is the best guarantee of its merit that can be adduced. It bears evidence of having been written because the subject was chosen for this prize, and we miss in it the signs of the mastery of a subject that we are accustomed to find when an author is writing upon a branch of surgery that he has made his own by long study and thought. The book will commend itself to many readers by its brevity and the number of illustrations it contains; but for fulness of detail and thoroughness of description it is no rival of Mr. Henry Morris's work on the same subject, and in amplitude of references and statistical information it falls short of Brodeur's recent thesis. It contains, however, a plain statement of the main facts in this branch of surgical pathology, and a very brief and simple description of the various operations on the kidney.

OUR LIBRARY TABLE.

The Principles and Practice of School Hygiene. By ALFRED CARPENTER, M.D. With illustrations, pp. 368. London: Joseph Hughes. 1887.—We are informed in the preface that this volume was "primarily written for students in training for educational work, as well as for those occupied in preparing them for their future duties." It consists of two parts: the first relating to the construction and fitting up of schools, and the general management of the pupils considered from a sanitary point of view; and the second to the accidents and injuries incidental to school life, the more common diseases which occur among the pupils, and the measures which should be taken to prevent their spread. The first part contains much useful information, but might, we think, have been judiciously curtailed, especially as regards construction, considering the object with which the book was written. The chapters on dormitories, physical exercise, time allotted to study, and school desks and seats, are well deserving of study. The second part partakes much of the character of ambulance lectures and "first aid to injured," and, viewed as such, is too long and enters too much into detail. It would, in our opinion, have a strong tendency to induce masters to undertake too great a responsibility in the treatment of cases of disease or injury, and lead to serious results from delay in sending for professional assistance. We regret that Dr. Carpenter does not point out more forcibly the importance of obtaining skilled medical advice in the early stage of illness, or in injuries, particularly those involving joints. The mischief arising from delay is often very great, and is not, we fear, generally appreciated. The book has the advantage of a good index.

Veterinary Science: a Sketch. By GEORGE FLEMING, LL.D., F.R.C.V.S., Principal Veterinary Surgeon to the Army. Pp. 16. London: Hazell and Co., 1887.—This paper, which is a reprint from the *Veterinary Journal*, gives an interesting account of the progress of veterinary science from the period of the formation of the first veterinary school in 1761 to the present time. On the advice of Bourgelat, an advocate at Lyons, Bertin, the prime minister of Louis XV., was induced to establish a veterinary school and school of equitation at Lyons, of which Bourgelat was appointed director. In 1766, under the auspices of the prime-minister, Bourgelat founded a second school at Alfort, and a third was subsequently organised at Toulouse; all three are still flourishing. Shortly after the formation of the school at Alfort one was established at Vienna by order of Maria Theresa, and the example thus set was quickly followed by Prussia, Denmark, Italy, Sardinia, Saxony, and Hanover. In 1791, through the efforts of the Odiham Agricultural Society, the first veterinary school in this country was established in London, under the title of the Veterinary College of London, and M. St. Bel, who had been trained at Alfort, was appointed the first professor. The college, under the superintendence of Professor Coleman, who succeeded M. St. Bel on his death in 1793, received much valuable aid from some of the most distinguished members of our profession, of which he was himself a member, including, among others, Sir Astley Cooper, Sir Charles Bell, Dr. Babington, Dr. Bright, and Sir Benjamin Brodie. In

Digitized by Google

1819 a veterinary college was established in Edinburgh by Professor Dick, who, at his death, in 1866, left a considerable sum of money to the college, vested in the Lord Provost and Town Council as trustees. In 1844 the veterinary surgeons obtained a charter of incorporation under the title of the Royal College of Veterinary Surgeons, of which Dr. Fleming is at present the President. In this historical sketch the author directs attention to the valuable lessons which may be learned in our profession from the study of comparative pathology, and "the advantages which human medicine must derive from careful observation and investigation of the diseases of animals." The great importance to the nation of sound veterinary science and skill may be estimated by the fact that "two exotic bovine diseases alone (contagious pleuro-pneumonia, or lung disease, and foot-and-mouth disease) have been estimated to have caused a loss during the first thirty years of their prevalence in the United Kingdom of 5,549,780 cattle, roughly valued at £83,616,854; while the invasion of cattle plague in 1865-66 has been calculated to have caused a money loss of from five to eight millions of pounds.

A Systematic Handbook of Volumetric Analysis. By FRANCIS SUTTON, F.C.S., F.I.C., Public Analyst for the County of Norfolk, &c. Fifth Edition. London: J. and A. Churchill. 1886.—Another new edition of a book so well known and so universally esteemed among scientific men as Sutton's Volumetric Analysis scarcely requires notice. The author has evidently spared no pains to incorporate all the more important of the additions which every month brings to our analytical resources. Among the additions in the new edition may be mentioned some newly devised and simple methods of gas analysis, and a synopsis of the valuable researches of Mr. R. T. Thompson on the indicators used in alkalimetry. These are merely quoted here as samples of the new matter with which Mr. Sutton's industry has enriched a book which is essential in every laboratory, and for which every chemist feels grateful.

The Gas Engineer's Chemical Manual. By J. ALFRED WANKLYN, Hon. Fellow of the Chemical Society of the University of Edinburgh, &c. London: The Scientific Publishing Company (Limited). 1886.—Mr. Wanklyn has, as usual, produced a good, and in some respects an original, little book. It is not without faults, but it will probably be more useful to the gas engineers, for whom it is designed, than a more elaborate scientific treatise. The methods of analysis described are within the range of skill commonly found in gasworks, and if the author prefers methods of his own devising, who shall blame him? The book is short, simple, and handy. New ideas and new systems are hardly touched upon, with the exception of the coal-liming process of Mr. Cooper. Gas engineers ought certainly to be grateful to Mr. Wanklyn.

The Organic Materia Medica of the British Pharmacopœia. By W. SOUTHALL, F.L.S. Fourth Edition. London: J. and A. Churchill. 1887.—We are glad to find that this unpretending little volume has reached a fourth edition. It contains a great deal of useful and practical information, not only on materia medica, but on pharmacy and pharmacognosy. The author has not confined his attention to the British Pharmacopœia, but has consulted other works of reference. The articles are well arranged, and are thoroughly reliable. The book is intended for medical and pharmaceutical students, and will be found useful.

The Year-book of Pharmacy for 1886. By LOUIS SIEBOLD, F.I.C., F.C.S. London: J. and A. Churchill. 1887. It is always a pleasure to record the appearance of this well-known Year-book of Pharmacy, which contains not only the transactions of the British Pharmaceutical Conference, but also abstracts of a number of valuable papers and articles relating more or less to materia medica, chemistry, pharmacy, and pharmacology. The present volume contains a great deal of useful information respecting lanoline, kairine, terebene, acetophenone, urethane, and other new drugs. Mr. Siebold has performed his editorial duties with his usual care, and the work is thoroughly trustworthy.

IRISH MEDICAL ASSOCIATION.

THE forty-eighth annual general meeting of the members of this Association was held at the Royal College of Surgeons in Ireland on the 6th inst., presided over by Dr. Kinkead. The report of the Council referring to the Medical Acts Amendment Bill of 1886, which has now become law, considers its provisions disappointing, inasmuch as they fail to protect the profession against practice by unqualified persons, and perpetuate an excessive and unnecessary number of licensing bodies granting qualifications to practise, of diverse educational grades, and without any settled standard of competency. In a recent report the committee of Council expressed a hope that a Bill to amend the Superannuation Act would soon be introduced into Parliament; but after considerable discussion it was agreed that it would be useless to ask the Government or any private member to introduce a measure of the kind unless the opposition of the Irish members could be overcome or their support counted upon; and that support, it was considered, could not be obtained in view of the facts that the Irish members chiefly represented the interests of the boards of guardians, which were generally hostile to allowing any powers to be taken from them, and further, that several of the Irish members had most strenuously opposed the Bill to amend the Superannuation Act previously put forward in Parliament. The Council had pleasure in stating that further cases of successful applications by medical witnesses at Court had been made for more equitable fees and expenses than were allowed by the rules of the committee of judges authorised to fix them. In opposition to the attempts made during the past year by the guardians of some districts to reduce the salaries of their medical officers, the Council were successful, the Local Government Board having refused to sanction the proposed reductions. An amendment to the report was adopted in reference to that portion of it bearing on the superannuation of medical officers, to the effect that the leaders of all parties in Parliament should be consulted to ascertain their views as to the terms of a Poor-law Superannuation Bill, which would receive their co-operation. The following resolutions were adopted:—

"That it would be but simple justice to the medical officers holding Poor-law or other medical appointments, and would tend towards increasing the efficiency of the service, that they should be entitled to a reasonable period of leave of absence in each year, as in the case of civil servants, and that provision for the same should be made at the public expense."

"That this Association requests the Council to avail themselves of the first favourable opportunity of introducing to the notice of Parliament a suitable measure, with a view to reasonable amendment of the law relating to superannuation of Poor-law medical officers."

The President stated that the result of the scrutiny of the voting papers showed that Mr. H. Gray Croly had been elected to the post of president of the Association for the ensuing year. The members and their friends dined together in the evening in the Albert Hall of the Royal College of Surgeons.

BIRMINGHAM AND MIDLAND SKIN AND LOCK HOSPITAL. The report presented at the sixth annual meeting of the governors of this institution on the 9th inst. showed that during the past year the number of new cases had been 2038—an increase of 41 on the number of the previous year. The finances are in a satisfactory condition, the balance of income over expenditure being £466. The building fund, for which a total of £6000 is needed, amounts to £4000, but it was decided not to commence the work until the remaining £2000 has been subscribed.

THE LANCET.

LONDON: SATURDAY, JUNE 18, 1887.

AFTER the meetings of the last two weeks, rich in speeches by the best men in every denomination and by leaders in the City and in the State, a common excuse for a poor collection to-morrow will not hold. It will not do any longer to say that an inadequate collection arises from ignorance of the case. The support of hospitals has been an affair with which the run of people, even kindly people, have been apt to think they had nothing to do. It was supposed to be secured by the piety of ancient founders; as if the generosity of one century could do the work of the generosity of another, and as if the piety of a man like GUY was to supersede the benevolence of whole future centuries. It is true of GUY that he actually did, with some assistance from another man of benevolent nature, supply for more than a century the magnificent accommodation to the sick for which Guy's Hospital has been famous throughout the world. But experience shows that men like GUY are of rare occurrence, and that the wants of the sick and the poor of any one generation must for the most part be met by their more fortunate contemporaries. We cannot rely on ancient endowments for the urgent work of relieving the sick that are about us to-day. Even Guy's itself is asking for help, and has a large part of its beds out of use for want of funds. The one good thing about the impecuniosity of Guy's is that it tends to rouse attention to a lamentable failure of public charity. The failure is to the extent of £100,000 a year—i.e., the excess of the expenditure and liabilities of the medical charities of London last year exceeded the ordinary income by £100,000. This sounds a large sum; but it could easily be put into the collection to-morrow without there being a dinner party less in London or the curtailment of summer holidays by one day. Anyhow, there it is staring us in the face. The ministers of religion have a rare opportunity to-morrow. By a sort of providential arrangement they have the Sunday before the great Jubilee day, when the feeling of national and metropolitan gratitude may be expected to require religious and substantial expression. They will not make light of the opportunity. The care of the churches is on their shoulders, and this presses heavily enough. But, as the Bishop of LONDON said at the Mansion House, we cannot pretend to be Christians while we make light of the claims of the sick. The very note of the Messiahship was that the sick were healed, the lame made to walk, and the blind to see. Such services are rendered every day in London hospitals. As far as the services are medical, they are mainly gratuitous. All that the public and the churches are asked to do is to find beds and maintenance and surgical instruments, while the beneficent work of medicine is being done. The Rev. Dr. ALLON justly traced the sentiment of humanity further back, even to the earliest traditions of religion and the scriptures of the Old Testament—a view confirmed by the fact that in this great anniversary Jew and Christian co-operate heartily together, and the Chief Rabbi is as earnest as the Archbishop of CANTERBURY. At one of the hospital meetings it was estimated that if the London churches gave in the same numbers and on the same scale as those of Birmingham the sum raised would be nearer £200,000 than £40,000. Surely the metropolis should not be beaten by a provincial town—even though it be Birmingham, where Hospital Sunday was first instituted. Two churches in London supply nearly a twentieth of the whole collection, and Dr. ALLON showed that the average sum raised by the London congregations is £20 each. He is no mean authority on the power of churches, and of what he called at the Mansion House the "voluntary principle." But he did not speak as if he thought that the churches had done all they could or should do, and he very powerfully contrasted the pleasure of giving to hospitals out of kindness and being made to give by a municipal or parliamentary rate. We heartily emphasise this difference, and recognise on behalf of the medical profession the pleasure of co-operating with the public in a divine and charitable work. There is no abuse in hospitals which does not admit of correction, and no correction of abuses will diminish the amount at present wanted for dealing with urgent cases. In fact, thousands of urgent cases are kept out of hospitals for want of funds. Every medical man knows this. Cases have to be turned out of hospitals prematurely, either to undergo a slow convalescence, or to die in the straitened homes of the uncomplaining poor. Thousands more are never admitted that an ampler charity would admit and greatly benefit. The life of hundreds is handicapped by chronic sufferings that might be alleviated or removed by a few weeks of hospital treatment, which in the present state of hospital funds cannot be given. These facts scarcely come out in statistics. They have to be ascertained by personal experience of the life and death of the poor, and must be taken on testimony. But they are facts all the same, which a very slight exercise of the imagination will make obvious to those who have hearts.

We must leave preaching to ministers. We must, from our point of view, state mainly the medical side of the case. But it is very strong. With all the labours of philanthropists and political economists, life is still hard, and there is still much disabling disease among the poor. Of all uses of wealth none is better than the support of institutions for the mitigation of pain and disease. If we cannot all do as much as GUY did, we can all do work of the same kind; and in doing it we shall do much to hold society together and to make the poor feel thankful to GOD for the existence of the rich. Active measures are in contemplation for eliminating all abuse from hospitals and leaving them free to deal with grave and urgent forms of disease.

NOT a little confusion has occurred, and much misapprehension has been occasioned, by the misuse of the term "medical peerages," instead of "peerages conferred upon medical men." We do not think it has ever entered the head of any sane member of our profession to propose the institution of medical peerages properly so-called. Until quite recently there were no special peerages. Even the fact that certain prelates of the Established Church had seats in the House of Peers did not make their peerages spiritual in a technical sense, although they were "lords

Digitized by Google

spiritual." There are now constructively a few legal peerages, but it would be preposterous to ask for the creation of peerages which should be medical. No such desire exists. All we wish, and the profession as a whole demands, is that the reproach which certainly attaches to the fact that no medical man has ever yet been considered worthy of a peerage, and that therefore it would seem to be held that there is something in the calling of, or profession of, the art of healing which is incompatible with the dignity of high social rank, should be wiped away. Surely it is not true that physicians and surgeons, as such, are incapacitated for social distinction? We cannot believe that such a notion prevails in the highest circles. It would be monstrous in these days, when success of almost every sort is recognised as a claim to honour, that the attainment of a prominent position in the service of humanity in the matter of health should be held to specially disqualify a man for distinction. It has, indeed, been contended that the position of the physician and surgeon is so peculiar that it must be regarded as *infra dig.*, he being, as it were, a personal attendant on the sick; but this view, if it were ever actually entertained, must have been so at a time and among persons when and by whom the nature of scientific medicine and surgery and the character of their practitioners were strangely misunderstood. It is no idle pretence to affirm that, taken as a body, the medical profession is not either less well educated or less able to bear the dignity of seeing some of its members raised to the peerage than other professions. The Church, the Military and Naval Services, and the Law are not intrinsically more honourable or of greater service to mankind than are Medicine and Surgery. It is hardly worth while to argue the point. Every unprejudiced person must, we think, agree that such rank as is freely accorded to ecclesiastics, soldiers, sailors, lawyers, men of letters, artists, and a host of successful merchants and manufacturers, cannot be reasonably denied to medical men—at least on the ground of their calling.

We have not the slightest wish to take up a narrow class position on this subject. If there be any solid reason why medical men should not be made peers, we are perfectly willing, and even anxious, to hear and recognise it. We can only say that as yet we have utterly failed to discover any such reason. It will probably be admitted that there is no rational objection to the elevation of medical men to the peerage. Then how does it come to pass that no member of the profession has ever been endowed with a coronet? Will it be alleged that no medical man has ever done anything to deserve so high an honour? Are there not now living members of our profession whose services to the State and the people, whose contributions to the prosperity of the nation, have at least equalled those rendered by some non-medical persons who have been ennobled? It would be mock modesty and argue a very inadequate sense of self-respect if we were to hesitate one instant in making the unqualified assertion that the merits of medical men, as such, are quite as tangible as those of members of other callings which have been duly honoured. Again, we may be told that medical men are, as a rule, too poor to be made peers. Possibly that objection may, though we do not say it ever could, have been held to be a good one in past times; but looking to the way in which peerages have been distributed during the last twenty years, or more, it cannot be seriously contended that great wealth is an absolutely indispensable qualification for membership of the House of Peers. There are, if we mistake not, some among us who are sufficiently provided with the means of maintaining the dignity of a peerage. Indeed, we can confidently state that there are at least three leading members of the profession who are possessed of an income of not less than £10,000 a year from invested property.

We would respectfully but firmly submit to those who advise Her Majesty in this year of jubilee that the occasion is one which offers an excellent opportunity for the redress of what is felt to be a grievance, in the nature of a great slight, by a section of the community which is considerable, both in point of numbers and social position and influence. By conferring a peerage on some one or more of the leading members of our profession, Her Majesty would create a worthy precedent, and do a just and generous action. We do not for a moment suppose any living physician or surgeon desires to be ennobled; we do not even know that anyone would accept the offer of a coronet; but the offer might be made, so that, at least, the profession may know that it is not wholly given over to social neglect. That good would result from the presence of one or two medical men in the Upper House cannot be doubted. The need of a direct representation of the claims of health on the State is daily becoming more apparent. Moreover, it would tend generally to raise the status and tone of the profession as a whole if its claims to well-deserved honours were recognised more generously.

LAST week we commented on the Bills purporting to deal with Adulteration which are now before Parliament, and on the complaints of some of the public analysts in regard to the present and future position of the Chemical Department of the Board of Inland Revenue. But the subject is too extensive to be discussed in a single article, and there are still some remarks which in the public interest it is our duty to make. We do so with all freedom because we have no bias on one side or the other, and are only anxious that, to use a phrase common in Acts of Parliament, the best practical means shall be adopted for the suppression of the trade frauds which are still rampant, in spite of the valuable work accomplished under the Sale of Food and Drugs Act of 1875. Happily the more noxious kind of adulteration which was so rife in 1851, when we undertook our inquiries, has to a great extent been suppressed, and has for the most part become too dangerous to tempt the unscrupulous trader. We cannot say that it has entirely disappeared, because the existing Acts are so irregularly administered that certainty is impossible, but it has undoubtedly been very greatly reduced. The other kind of adulteration, however, by which the purchaser, though not poisoned, is cheated, is still so common that some alteration of the law is imperatively called for. In respect of some articles, indeed—as, for example, milk and drugs—trade frauds involve a very serious danger to public health, and have exercised a prejudicial effect upon it. The child fed on watered milk is fed on food of unknown, and therefore in many cases of insufficient, strength.

The Bills now before Parliament deal with two articles

Digitized by Google

only—beer and butter. We have already stated our views in regard to the first of these. No false description of or deleterious addition to beer can in any case be tolerated, and the revenue must of course be protected; but subject to these conditions, we see no reason for limiting the materials used in the manufacture of so artificial a beverage. Competition will regulate the price, and any artificial restriction would only add one more to the sumptuary laws which have in all ages proved failures. The case of butter is somewhat different. There can be no difference of opinion as to what in popular acceptation constitutes butter. It is a semi-solid, prepared from milk only, but containing naturally and unavoidably a considerable quantity of water. The addition of salt and of a minute quantity of some harmless colouring matter is justifiable; but foreign fats, such as are grouped together under the names of butterine and oleo-margarine, are not butter, and their sale therefore as butter is a palpable fraud. But even to this apparently simple story there is another side, which must not be forgotten. It seems certain that these butter substitutes are as wholesome and fit for food as butter. They are much more palatable than the cheaper kinds of genuine butter, and they can be sold at a profit at a cheap rate. But for prejudice they would be asked for and used freely by thousands of families, and but for their illicit use butter would be much dearer than it is at present. It is freely admitted that their sale under the name of butter is at present a fraud, but nevertheless it is a fair question whether it might not be better to destroy the fraud by legalising it. Popular prejudice is entitled to some consideration. We know perfectly well that it will be long ere a housewife can be induced to ask boldly for a pound of oleomargarine. She may suspect that the very cheap fresh butter she buys, pleasant though it be in taste, cannot trace an unbroken lineage from the cow; but she naturally clings to the name with which she is familiar, and would shrink from the idea of offering her children bread and oleo-margarine. Would it not be better to respect her sentiment, and to leave the price of butter, like the price of beer, to be settled by the ordinary laws of trade competition? It would be easy to protect those who want, and are willing to pay for, genuine milk butter. Let a new word be introduced, and let everyone be warned that if he objects to substitutes he has only to ask for "milk butter," and he will either get it or be egregiously cheated. The detection of foreign fats in butter is now so easy, thanks to the labours of the public analysts, and above all to those of Mr. OTTO HEHNER and his former *confrère*, Mr. ANGEL, that adulteration of butter sold as milk butter could easily be made too dangerous to pay.

Of much greater importance is the question of drugs. The patient is practically at the mercy of the dispenser, and the dispenser depends on the merchant, who may or may not be the manufacturer. The manufacturer commands the situation, for the dispenser cannot analyse every drug which he receives. So it happens that, although most manufacturers and dispensers are honest and careful, any individual patient runs the risk of losing all the benefit of medical treatment through the imperfection of the drugs administered to him. The only standard that can be set up is evidently that of the British Pharmacopœia, and even this must be used with discretion, for some drugs are so unstable that it is impossible to keep them for any time without deterioration. It would be for the public benefit that all important drugs should be frequently analysed by some impartial chemist, but in many cases a warning instead of an immediate prosecution would satisfy justice. The adulteration of quinine is one thing, the defective strength of hydrocyanic acid quite another.

The real remedy for the present uncertainties and irregularities of the law can only be found in a new and efficient Food and Drugs Act, framed on the basis of the present. We are prevented by limits of space from stating in sufficient detail our ideas of the Act as it should be. But a few of the salient points may be sketched. The Act should be not less wide than it is now, and ought to include in its purview all adulterations of food or drugs, whether noxious or merely fraudulent. The powers of the central authority should be considerably strengthened, and it should be able to compel the enforcement of the law. A large number of local authorities do their duty thoroughly, and it would be unwise to interfere with them; but others do nothing, or next to nothing. In many places no analyst is appointed, and in others no work is found for him to do. Such authorities must be coerced if the public is to be protected. Opinions will differ as to the best way of securing the administration of the law, but one way is obviously possible. Having compelled the appointment of efficient public analysts in every district, the Local Government Board might have power to insist that a sufficient number of properly selected samples should be sent for analysis. If this duty were systematically neglected, the Board should be able to appoint their own inspector, and to charge the offending district with the expense. The regulations for the collection of samples require thorough revision. We quite agree with Dr. BELL of Somerset House that the inspector should have the power to enter premises and select his own samples, dividing them into portions, and paying for them as at present. Sometimes, as in the case of beer, large samples are required, and there is in all cases a risk that the vendor, knowing the inspector or his envoy, or guessing at the object of the purchase, may substitute a pure for an adulterated article. All articles of food and medicine should be included under the Act, whether subject to excise duty or not. There need be no conflict between the public analysts and the excise chemists. The main duty of the latter is the protection of the revenue; but an analytical department is necessary for this purpose, and we see no reason why the Government chemists should not continue to act as they do now as referees in disputed cases. Their powers should be more accurately defined, and some arrangement should be made with regard to perishable articles, such as milk, the analysis of which can never be quite satisfactory unless made upon a fresh sample. Finally, the new Act should contain a carefully drawn schedule in which the principal articles of food and drugs were defined, and limits of purity assigned. With regard to drugs this can easily be done by referring to the British Pharmacopœia as a standard. Food will occasion more difficulty, but none that need be insuperable after the experience that has been gained in the last few years. Milk, butter, and beer are the articles which have given rise to most controversy. In this and our last week's

Digitized by Google

article, we have considered the last two, and we have often stated our views in regard to milk. To the public analyst is at present assigned the impossible task of ascertaining how much water has been added to or how much cream removed from milk, and as milk is sometimes naturally very poor, he is compelled to take a low standard of purity. The Act might properly provide that milk should be held to be adulterated if it did not contain as much as 3 per cent. of fat and 9 per cent. of solids not fat, or if it contained any substance foreign to milk. The offences of watering and skimming could then be detected with certainty, and the public would be secure of getting good if not very rich milk. At present the limits used by most public analysts are 2½ per cent. of fat and 8½ per cent. of solids not fat, which represent a very poor milk.

THE question of the sanitary condition of India has been brought prominently before the British public by the publication in *The Times* of a letter by Mr. Justice CUNNINGHAM, a judge of the High Court of Calcutta, and by a leading article in that journal. Our readers must be well aware that this is no new subject to us, as we have repeatedly brought it under their notice in our reviews of the annual reports of the Sanitary Commissioner with the Government of India, and of the Health Officer of Calcutta. We rejoice that this important question has been raised by so high an authority as Mr. Justice CUNNINGHAM, and backed by the powerful advocacy of the leading journal, because it cannot fail to conduce to some more active measures of improvement than have hitherto been in operation. But to some of the statements which have been made we feel bound to take exception, believing, as we do, that nothing tends so much to retard sanitary improvements as an exaggerated representation of the need of them and of the benefits to be expected from their adoption. Thus, we are told that, "according to Professor MACLEAN, from the time of the commencement of our occupation until about 1860 the mortality of the English troops 'oscillated round' the enormous figure of 79 per 1000; and this frightful death-rate was, within a few years, reduced to reasonable proportions by the adoption of the recommendations of the Royal Commission of 1859-60. In 1882 the English military death-rate was only 13·07 per 1000 from all causes." Now, this comparison is entirely misleading, as it refers to two bodies of troops serving under totally different conditions. In the first period the British troops consisted of men enlisted for service in India, who remained there, unless invalided home as unfit, until they died or had completed twenty-one or twenty-four years' service; while in the later period they were men of the regular army, who were retained in India only ten years, and for the invaliding of whom, if their health broke down, much greater facilities existed than formerly. Those only who have studied the influence of age and of length of residence upon mortality in India will be able to appreciate the important part this change has played in the reduction of the death-rate. We by no means undervalue the influence of sanitary measures upon the health of the troops or of the civil population, but we believe they will carry more weight and be more likely of adoption when carefully and correctly estimated than when supported by inaccurate data.

Mr. Justice CUNNINGHAM in his letter calls attention to the valuable work being done by the Public Health Society of Calcutta, in its endeavours to popularise sanitary knowledge, and to bring forcibly to the notice of Government the evils of the existing state of things, and the improvements necessary for the introduction of efficient sanitation. But we are disposed to think he has not done justice to the sanitary commissioners and health officers, who were working zealously in this direction before the Society was formed; nor to the late Lieut.-Governor, Sir RIVERS THOMPSON, for his firmness in enforcing sanitary measures in Calcutta; and those European residents, of whom Mr. Justice CUNNINGHAM himself was one of the most energetic, who pressed upon the Government the necessity for active intervention.[1] The letter of Mr. CUNNINGHAM points out forcibly the failure of the Municipal Corporation of Calcutta, apparently from want of knowledge of, and belief in, sanitary science, to carry out to a sufficient extent the measures necessary to ensure the health of the population; for, though they have effected some improvement, much yet remains to be done. "While cholera has raged in the insanitary portions of the city—the cholera mortality in some wards attaining for some weeks ratios beween 18 and 36 per mille per annum—the properly conserved portions of the town have enjoyed practical immunity from the disease."

The measures proposed by Mr. CUNNINGHAM for the improvement of the sanitary administration in India are—1. The creation of a body possessed of sufficient knowledge, and armed with sufficient authority, to superintend and control the municipalities in the performance of their duties, and to enforce that performance in the case of persistent neglect or contumacy. 2. A recurrence to the system of Government itself lending the necessary funds to municipalities who have to borrow in order to carry out structural arrangements. 3. The creation of a branch of the Public Works Department whose special duty it shall be to assist municipalities in important projects of drainage or water supply, and to test the soundness of projects. 4. The creation of a staff of officials, sufficiently strong in numbers, ability, and resources, to conduct scientific investigations into disease with the precision and completeness that such inquiries necessitate, and which their importance justifies. He comments, with much justice, upon the inadequate and niggardly arrangement at present existing for scientific inquiries into sanitary questions, which appear to devolve upon "a single official, who receives an honorarium of £30 a month for devoting to microscopic research the small leisure left by his other professional duties. Even this scanty provision is intermittent." We most sincerely trust that the Government may see its way to a proper adjustment of the administrative machinery necessary for the promotion of the health of the people by the adoption of well-considered and efficiently worked sanitary measures. It is a matter which may involve a considerable outlay, but an outlay which we have no doubt will be more than repaid by its results. The improvement of the health of the people is an imperative duty of the Government, and one with which no paltry question of reduction of expenditure should be permitted to interfere. A liberal but judicious expendi-

ture for such a purpose would prove ultimately to be true economy, tending to promote the prosperity of India and the moral and physical well-being of its population.

THE custom of using unqualified practitioners, especially in branch practices, and in situations where the assistant cannot have any guidance or supervision from the principal, has had many severe discouragements of late, but none, perhaps, more so than one involved in a judgment in the Queen's Bench by Lord COLERIDGE and Justice DENMAN in the case of HOWARTH *v.* BREARLEY, reported pretty fully in *The Times* of June 13th. The question raised by the case was whether for services rendered by an unqualified assistant employed by a registered medical practitioner the principal or his representatives could recover in a court of law. The case was begun in an action in the Salford court by the assignee of Mr. FITZMAURICE, a qualified medical practitioner at Bury, to recover from a person near there a sum of £18 12*s.* for medical attendance and medicine for a period from 1880 to January last. It was admitted that the actual attendance was by an unqualified assistant, Mr. FITZMAURICE himself taking no part. At the first trial it was objected that under the 21 & 22 Vic., c. 90, the plaintiff could not recover, as the attendances were by an unqualified person. The judge took this view, and directed a nonsuit. On the present occasion there was an application to the Court of Queen's Bench by way of appeal from that decision. There was a sharp difference of opinion, or, at least, of argument, sustained with much liveliness, between Mr. WILLES CHITTY and Lord COLERIDGE. Mr. CHITTY maintained that the attendances in law were by the principal. He admitted that there was no personal attendance on the part of the principal, but maintained that through the agency of the assistant, who lived at a branch house, he attended the patient. He admitted that the unqualified assistant could not recover for this, but contended that the principal could. Lord COLERIDGE, with much animation, controverted this view, which, he said, would defeat the whole object of the Act, which *is to prevent unqualified persons from acting*. This is, perhaps, rather too absolute a way of putting it. If the Act of 1858 had been expressly designed to prohibit unqualified practice, it would have been very different in its penal clauses from what it is. But it certainly gives such persons no power of recovering fees. It does not recognise their right to make charges, and it prohibits the false use of medical titles, and in this way it discourages unqualified persons from practising; but it does not absolutely prohibit them. Lord COLERIDGE was decided, however, in his view. He entirely supported the judge below who had directed a nonsuit. The medical man whose representatives sued had not rendered the service sued for, and he could not recover, and therefore the nonsuit was right. Mr. Justice DENMAN was equally strong in supporting the non-suit. He said: "The medical man here did not show that he had rendered the services sued for, and so he could not recover. The services sued for were rendered by another person, who was unqualified, without any consultation with him. It was urged that this person acted as his servant; but a qualified practitioner could not thus authorise an unqualified person to act for him in medical attendance. It would be a mockery to apply the doctrine of master and servant to such a case, and it would entirely defeat the intention and object of the Act." The appeal was accordingly dismissed.

This judgment will clear the air a good deal. Some previous cases seem to have been decided in an opposite sense, or at least in a doubtful sense. But the opinion of Lord COLERIDGE and Mr. Justice DENMAN, given with so much clearness, is likely to settle this question. And, indeed, any other view of the case would be as disastrous to the profession as it would be absurd. If a medical man were at liberty to officer half a dozen branch houses or dispensaries with as many unqualified assistants and to enforce payment for their services in a court of law, the practice of unqualified persons might be indefinitely increased and encouraged to the great injury of the public. Such a doctrine would not only cover conduct which the Medical Council has severely condemned, but it would legalise it. We are much gratified, therefore, at the decision given in the High Court, from which it follows that charges for all services rendered by unqualified assistants alone cannot be recovered.

Annotations.

"Ne quid nimis."

THE APPROACHING COLLEGE ELECTION.

THE following gentlemen are candidates for the vacancies on the Council of the Royal College of Surgeons caused by the annual retirement of members:—Mr. John Couper (Memb. 1859; Fell. 1861), of the London Hospital; Mr. Alfred Willett (Memb. 1859; Fell. 1862), of St. Bartholomew's Hospital; and Mr. Brudenell Carter (Memb. 1851; Fell. 1864). Sir T. Spencer Wells, Bart., and Mr. Jonathan Hutchinson, two of the members retiring in rotation, seek re-election; but Mr. John Wood will not again come forward. The last day for the reception of nomination papers was Monday last, *June* 13th, and not *July* 13th, as was accidentally stated in our last issue. The voting takes place on July 7th, at 2 P.M., in the library of the College.

SUCCESSFUL REMOVAL OF A TUMOUR FROM THE SPINAL CANAL.

ON Thursday, June 9th, Mr. Victor Horsley removed a tumour from the spinal canal of a gentleman aged forty. The diagnosis of compression of the spinal cord by a morbid growth was made by Dr. Gowers, who saw the patient with Dr. Percy Kidd. The patient was suffering from paraplegia, which commenced gradually six months ago, and from pain round the chest of four years' duration. Sir William Jenner afterwards saw the patient, and confirmed the diagnosis. Dr. Gowers suggested that an attempt should be made to remove the growth. From the history of severe neuralgic pain in the back and along the course of the left sixth dorsal nerve which preceded the paraplegia, it was considered probable that the growth commenced in the posterior root of the nerve, and afterwards produced pressure on the cord. The operation was performed by a long incision in the mid-line of the back, having its centre about the fifth dorsal, down to the spines of the vertebræ. The muscles were cleared off from the laminæ and retracted. The spines were removed by bone forceps, and then the laminæ trephined. An incision was made

Digitized by Google

through the membranes and the cord examined, a tumour about the size of the tip of the little finger being eventually found on the posterior root of the nerve about the level of the third dorsal vertebra. This had pressed the cord forwards and to the right, producing a deep depression in its substance. It was removed with the nerve to which it was attached. The incision through the membranes, which was at least three inches long, was not sutured; the wound in the soft parts was closed with sutures and drained. Strict antiseptic precautions were taken at the operation. Since the operation there has been no rise of temperature, and the pain has diminished. The painful spasmodic action of the muscles of the lower extremities from which the patient suffered has diminished, and there has been less rigidity of the legs, but the paraplegia continues. The growth, which was of a pinkish colour, elastic and vascular, has not yet been submitted to microscopical investigation.

EXPERIMENTAL NEURITIS.

HYPODERMIC injections of ether are now so frequently employed, and with such good effect, that we are apt to forget that occasionally nervous lesions result from their use. Cutaneous anæsthesia, disorders of motility, and even serious trophic lesions have been observed, and the experimental researches of Arnozan and Salvat proved that the mechanism of these lesions was a peripheral neuritis. MM. Pitres and Vaillard find, however, that some of the peculiarities of the action of ether on the peripheral nerves must have escaped the attention of the last-mentioned observers.[1] We reproduce the salient points of this interesting communication. When an injection of half a cubic centimetre of sulphuric ether is made deeply into the cellular tissue which separates the muscles on the back of the thigh of a guinea-pig, there always results a paralysis of sensation and motion in the parts of the limb situated below the level of the injection. Generally the anæsthesia occupies the two outer toes and the outer aspect of the leg, but it may sometimes affect all three toes and the whole of the skin of the leg, probably because the injection has traversed the muscular interstices and attacked the crural nerve. After a few days these phenomena may be accompanied by œdematous swelling of the foot, ulceration of the toes and tarsus, falling off of the nails, &c. The anæsthesia and the paralysis are manifested immediately after the injection, and in a short time they have reached their fullest extent, and, once developed, they persist for several weeks or even months without either increasing or decreasing in severity. In order to study the mechanism of the action of ether, MM. Pitres and Vaillard have made a histological examination of the segments of the nerve situated above, below, and at the level of the injection of ether, and these examinations have been made on the sciatic nerve from animals after a survival of some hours, days, or several weeks. Above the zone of injection the nerve has always appeared absolutely normal; nothing like an ascending neuritis has been observed. At the level of injection the alterations varied according to the length of survival of the animal. When the nerve was examined some hours only after the injection, this nerve being teased after maceration for twenty-four hours in a solution of osmic acid, and coloured by picrocarmine, eosine, or hæmatoxylon, the myeline is found to have become blackened and rather different from the bluish-black tint of normal nerve fibres. Further, the lateral fissures are no longer to be seen, the axis cylinder and nuclei of the internannular segments are not distinct, and it seems as though the nervous elements had become altered in their chemical composition. If the animal be killed six, eight, or ten days after the experiment, the segment of affected nerve shows the same changes; it is only after the fifteenth day that the altered fibres begin to undergo notable modifications: the myeline breaks up, and is slowly absorbed. Below the level of the injection the nervous tubules proceeding from the nerve trunk affected by the ether undergo the Wallerian degeneration, which is well marked on the fourth day. The ether is therefore regarded as causing an immediate necrosis of the nerve trunk at the site of injection. This was also shown by an experiment in which the nerve was first divided at its exit from the pelvis, and on the same day ether was injected into the lower part of the thigh of the paralysed leg. Wallerian degeneration was found eight days after in the nerve, between the point of section and that of injection, and also below the latter, but in the area of injection the nerve had not undergone degeneration; the myeline was continuous and confounded with the axis cylinder, and there were no traces of nuclear multiplication. Other experiments showed that an injection of the sulphuric ether could arrest the Wallerian degeneration at any point in its career. The same facts hold good with nitric and acetic ethers for guinea-pigs, rabbits, and cats. Hydrochloric ether has less severe effects. Formic and valerianic ethers have caused considerable local swellings and gangrene, thus preventing a proper examination of their action on nerves. The authors suggest that, in cases in which neurectomy or neurotomy is needed, injection of ether in the neighbourhood of the nerve trunk might serve equally well.

[1] Gazette Médicale de Paris, No. 22, 1887.

THE HOVE INFECTIOUS HOSPITAL.

WE have received a further communication from Mr. Henriques as to the Hove Infectious Hospital. We do not publish it because it no longer deals with the defects referred to previously; it merely brings forward a few fresh points of objection to the institution. One relates to the use of earth-closets, it being alleged that the contents are not buried "at anything approaching to a sufficient depth to be safe." Surely such a trivial point of local administration can be altered by an order that the man in charge is to dig deeper. Then it is stated that there is no system of drains. The drains themselves we believe to be well and properly laid, but we agree with Mr. Henriques in so far as the absence of a proper system for disposing of their contents is concerned. There is ample ground for this, and here amendment is certainly wanted. Then the water supply is complained of. The supply is derived from a neighbouring public reservoir, and, owing to the levels, it has to be stored in a second reservoir on the hospital site, and to be pumped by horse-power into the hospital cisterns. We are sorry that, owing to the position of the buildings, such an expense should be necessary, but we fail to see why such a matter should be held up as an objection to the hospital itself. "Stored water," we now learn, "is *never* pure," and it "*may*" become contaminated. These are not grounds of objection which merit the publicity which this question has received. In every way we regret the action taken by Mr. Henriques and his supporter General Shute, and in one respect it has been scarcely courteous. Thus, the latter publicly asserts that our comments were inspired by a local partisan, and hence to quote them in favour of the views of the medical officer of health as to the hospital is "simply giving the public credit for being idiots." And Mr. Henriques, referring to the suspicious character of certain dates, regards our comments as "inspired *ab extra*." We may state that our comments have been the result of a personal visit to this partial hospital provision for infectious diseases in Hove, and of a knowledge as to the principles properly governing such provision—which, we believe, is not inferior to that possessed by those who have done so much to bring the institution into public disrepute.

THE LATE DR. WAKLEY.

THE Executors of the late Dr. James Goodchild Wakley request us to note that he devised his freehold residence at Longcross, Chertsey, Surrey, with its stables, outbuildings, gardens, and pleasure grounds, about eight acres in extent, to University College, London, as a memorial to his late father, Thomas Wakley, Esq., M.P., and in commemoration of the establishment of THE LANCET, of which the late Dr. Wakley was for so many years the Editor and part Proprietor. The expressed object of the devise was that the premises might be used by the College as a Home for the reception and treatment of Convalescent Patients in connexion with University College Hospital, to be called the "Wakley Convalescent Home." He also bequeathed to the College the pictures and prints in the house, to be kept there for the amusement of the patients; and a pecuniary legacy of £1000, to be expended in the maintenance and support of the Convalescent Home at the rate of £200 per annum for the five years next succeeding his death. The Solicitors of the Executors inform us that the premises, with the pictures and prints, have been handed over to the College, and that the legacy has been paid. The late Dr. Wakley also made several other charitable bequests, all of which have been paid or set apart. Notably—to the Hospital Sunday Fund (which, in so far as London was concerned, was initiated by the late Doctor in his capacity as Editor of THE LANCET), £1000, in addition to two previous donations of a similar amount; to the poor of Sunningdale, £200; to the poor of Chobham, £500; to the Bisley Refuge Farm School, £500. And provision was made by the Doctor in his lifetime for the continuance for some years of the religious work among the poor in the neighbourhood of his residence which he had for long superintended.

CHOLERA FORECASTS.

WHETHER or not the German journals are warranted in anticipating a return, in greater force, of the cholera invasion that hovered round Mayence last autumn, they cannot certainly be blamed for treating June and July as the test months for the reappearance of the epidemic. A dry spring like that which heralded the cholera raids on Munich in 1836, 1854, and 1863 has no doubt been absent this year, but the suddenness of more recent explosions of the malady has lessened the importance to be attached to that condition. A vigilant prophylaxis, therefore, is all the more justifiable—a prophylaxis not guided by the worn-out traditions of French or Italian sanitation, but by the counsels of that sagest of hygienic strategists, Max von Pettenkofer. "Zum Gegenwärtige Stand der Cholerafrage" ("On the present Aspect of the Cholera Question") is the title of a series of papers just concluding in the *Archiv für Hygiene* (Munich: Oldenbourg), from the pen of that great authority, and the wholesome truths they inculcate must, if well acted on, "place Germany in as unassailable a position hygienically as her War Office headed by von Moltke has placed her in strategetically." Readers of THE LANCET will remember that von Pettenkofer, even after the second cholera conference at Berlin, saw no reason to modify his non-contagionist view of the origin and spread of the disease. While recognising with M. Koch a cholera bacillus, and *ex hypothesi* accepting that micro-organism as the parasitic basis of the malady, he denies the conclusion sought to be deduced from this theory that cholera is communicated by the contagium of the bacillus Kochianus. Malaria, he contends, has also a bacillus or a germ (vegetable or animal) for its basis, but it does not infect the human subject by contagium; it passes from the soil into the air, whence it reaches the organism through the lungs. Epidemiologically considered, cholera does not effect its foothold in localities by man-to-man contagium. Lyons, Innsbruck, Salzburg, the asylums to which cholera patients by the thousand have fled, have never contracted the disease; in fact, for really contagious diseases no localities can ever be called exempt, as these cities have been from cholera. It is, thinks von Pettenkofer, to the malarial group of epidemics that we must turn for the true analogy of the origin and spread of cholera, and the prophylaxis which that analogy prescribes—attention to the conditions of subsoil when operating in connexion with season—will be found to cut at the root of the outgrowth and spread of the disease. Contagionism with its isolation, its sanitary cordons, its quarantine, its disinfectants, has achieved nothing but *fiasco*. Witness 1884, when cholera, non-existent in Egypt, non-existent in Europe, exploded in France, and almost simultaneously, at Toulon and Marseilles, all M. Fauvel's contagionist machinery notwithstanding; witness the same year and the year following in Italy, where every contagionist precaution was enforced with fanatical strictness, and where nevertheless the malady had everything its own way in the frightful outbreaks. Yet so wedded was M. Fauvel to his contagionist theory, that on his death-bed he solemnly declared that the epidemic that had decimated Toulon and Marseilles could not have been Asiatic cholera because it proved intractable by his contagionist preventives! The practical lesson deduced from von Pettenkofer's findings is this: vigilant attention to the subsoil as to drainage, vigilant attention to water supply, such as within the next decennium Germany relies upon to make her as exempt from cholera visitations as her frontier is from attack. "Forearmed hygienically against the one and strategically against the other," she reiterates her claim to look on both with equanimity.

EPSOM COLLEGE.

THE alterations in the by-laws of this College which were proposed and carried at the last annual meeting establish the institution on a new basis. Hitherto Epsom College has been a class school confined almost entirely to the sons of medical men. A few day-boys were admitted, and only a small percentage of sons of others than medical men were among the boys. This limitation of Epsom College has done much to check the development and extension of the school. Parents have long since recognised that to limit a school to a particular class tends to curtail a boy's intellectual powers, and lessens his social advantages in after-life. Thus, other public schools—notably Wellington College and Marlborough—have expanded from the strictly military foundation of the one and the clerical foundation of the other into large general public schools. This should have been the object at Epsom. From the foundation of the College the disposition has been to make the medical benevolent feature of the foundation too conspicuous. The Epsom boys had at all times before them a not very encouraging emblem in the form of aged professional pensioners located in almshouses adjoining the College. These are found to be a mistake, for the occupants, if given choice, prefer their small pension and residence elsewhere to the precincts of Epsom College. Thus the almshouses are being gradually vacated, and are becoming utilised for school purposes. It would be to the interest of the College, and not to the disadvantage of the pensioners, if the whole of the almshouses were diverted to school purposes, and the proceeds arising therefrom directed to the benefit of the aged pensioners resident elsewhere. Hitherto the College, like some other public schools, has been weighted by a heavy debt. On his retirement from the treasurership of the College, it must have been a great satisfaction to Mr. Francis Hird to have been able to announce that during his period of office this debt had been entirely wiped out. Dr. Holman of Reigate succeeds Mr.

Digitized by Google

Hird as treasurer to an institution now unembarrassed and commencing a new era in its existence. Epsom College henceforth is to aspire to be a great public school, fitting boys not only to enter the medical profession, but other professions and the universities. Dr. Holman, on entering office, pledged himself to the governors present at the annual meeting that the sons of members of the profession should reap the full advantage of any extension of the school, and *this, too, at only a fraction above the prime cost of their education.* We place on record this assurance of Dr. Holman in order that it may not be lost sight of in what we hope will be a successful phase in the history of Epsom College. Each member of the profession is as much interested in doing for Epsom what he can, as military men have been in Wellington and clergymen in Marlborough. At these schools masters have been found ready to build boarding-houses for boys, and the same has been done at Charterhouse and Winchester. Epsom College may be extended in the same way, to the advantage of the foundation. But to this end scholars must be forthcoming from outside the profession, and at a rate of remuneration such as shall be a source of profit to the institution. The present happy position of Epsom College cannot but be highly gratifying to the members of the family of the late Mr. Wakley who are now conducting this journal, of which he was the founder. It will be remembered that a large memorial fund, subscribed after his death in 1862 by members of our profession, was presented to Epsom College, to establish a scholarship which should bear his honoured name.

ZIEMSSEN ON COLD WATER TREATMENT OF TYPHOID.

The *Journal of the American Medical Association* for May 14th contains a full abstract of a lecture on Antipyresis and Antipyretic Methods by Professor Ziemssen, director of the Medical Clinic of Munich, especially in regard to typhoid. The lecture is very interesting and earnest. It claims a high value for the treatment by baths, and expresses a hope that after the favourable results of active antipyresis physicans will not lapse again into the therapeutic indifference of the Vienna School. Of all antipyretic measures Ziemssen considers hydrotherapy the chief: first, because it combines in itself all the attributes of a remedial measure; and, secondly, because its action on the fevered organism may be varied to any degree. The benefit of such treatment is not confined to typhoid, but is also to be noticed in other febrile diseases, such as pneumonia, erysipelas, and acute phthisis. The cold and lukewarm baths act, he thinks, by cooling the blood at the periphery, the vital fluid being returned to the internal organs with an indescribably pleasant as well as beneficial effect. Sleep is favoured. There is an improvement in digestion, so that the patient can be fed better. On the circulation the effect is to contract the peripheral vessels, the heart works more slowly, the vessels show an improved tension, dicrotism is decreased, and the elasticity elevation returns. The respiratory apparatus is excited by the peripheral irritation to deeper and slower movements, cough is more effective, and in this way bronchial obstructions and consequent atalectasis and catarrhal pneumonia are better avoided than by the impracticable advice to turn a fever patient on his side. Ziemssen gives two or three statistics to show the effects of the cold and the lukewarm bath treatment respectively. He takes his illustration of the strictly cold bath from Vogl, physician to the Garrison Hospital at Munich. He gives (with a rectal temperature of 102·2° F.) a cold bath at 63·5°, lasting a quarter of an hour, about every three hours, winter and summer, in unheated rooms, with windows open day and night. This is bold treatment, and for soldiers (for the most part with young and picked lives) does well. There were only 52 deaths in 610 cases, or 5·4 per cent. Murchison gives the mortality of typhoid in the London Fever Hospital, after deducting cases which died within forty-eight hours of admission, as 15·82 per cent. Ziemssen compares Vogl's practice with strict cold water treatment with Naunyn's in a civil hospital, who, with an axillary temperature of 103·1°, taken every three hours, gives usually eight baths in twenty-four hours, generally between noon and midnight, at a *not lower* temperature than 72·5°. He divides baths into *cold* (72·5° to 81·5° F.; duration, five to ten minutes), *lukewarm* (from 81·5° to 90·5°, ten to fifteen minutes), and *warm* (90·5° to 95°). The warm are given in the later stages in very active delirious patients with great restlessness and muscular weakness. By this treatment Naunyn lost 10 of 145 cases, or 6·9 per cent, "certainly a favourable percentage." Ziemssen himself says that for twenty years he has recommended, for private practice, the gradually-cooled bath. The patient is placed in a warm bath of 90·5° or 86°. The water is continually poured over him with hands or sponge. While this is being done, cold water is very slowly poured in at the foot of the bath tub, and the water reaches gradually a temperature of 77° or 72·5°, until the patient's teeth chatter, or he declares he can stand it no longer. He is then taken out and placed in a blanket previously warmed, and wrapped in it without being dried. In this he remains in the greatest comfort for fifteen minutes, is then rubbed dry, and allowed to sleep. Ziemssen, like a wise physician, recommends the study of the peculiarities of individual cases. While lauding the bath treatment, he speaks respectfully of antipyretic drugs.

STATISTICS OF SUICIDE.

THE *Chronicle*, an enterprising journal in New York, has made a very painstaking compilation of statistics relating to suicide, culled from the daily press of America over a period of five years. In this way a large number of cases has been brought together, and although the sources of information are not always the best or the channels through which it flows the most trustworthy, yet the result presents many interesting features, and well repays the compiler's trouble. Among the most striking of the facts brought out is the very obscure influence of the season of the year upon the prevalence of suicide. It would be a curious experiment to poll a constituency of ordinary people for opinions on this point. We much suspect that autumn or winter would commonly be credited with being best adapted to develop and foster suicidal tendencies. In America it would seem that summer enjoys this unenviable pre-eminence. And not only so: the summer months all rank high—the highest in the year; but, actually, the highest of them all is "the flowery month" of June. On merely psychological grounds, it would seem quite unintelligible that suicide should be at its maximum just as spring is making way for summer. The reason must be sought elsewhere—in the organism and its environment; and possibly the circumstance that a very large proportion of the suicides are agriculturists affords a practical explanation. At least, this is the season of the year, just before harvest, when a farmer is likely to find himself most hardly pressed for money. The demand for money for agricultural purposes, which is so well known in our own money market as a regularly recurring feature of that season of the year, bears testimony to the existence of a state of things which, indeed, may be seen by the help of merely *à priori* considerations to lie in the natural and necessary course of events. It is very conceivable that this pressure in a country like agricultural America, where banking facilities, compared with ours, are very limited, may be pronounced enough to affect quite appreciably the suicide record of the agricultural class. This explanation does not seem, however, to be fully adequate, for, giving to

Digitized by Google

it the fullest weight possible, we still are face to face with the anomaly that a special circumstance is made to explain a very general feature of the figures given. It is probable that the truth lies deeper still in the nature of things and men, and must await for its full disclosure the more complete analysis of the relations between mental states and pathological conditions, and again between these latter and the season of the year. In the meantime these seasonal figures, being among the most reliable, presumably, that our contemporary has put together, are of sufficient interest to warrant reproduction.

Distribution in seasons of 8236 American Suicides.

Spring.		Summer.		Autumn.		Winter.	
March	649	June	833	Sept.	781	Dec.	627
April	687	July	746	Oct.	681	Jan.	538
May	706	Aug.	807	Nov.	600	Feb.	571
Total,	2042	Total,	2386	Total,	2062	Total,	1736

Of the suicides brought under review, nearly 6000 have been classified under causes. The results thus brought out agree more nearly with one's expectations. Insanity, of course, heads the list. Family trouble comes next, while business trouble, dissipation, and disappointed love rank almost together for the third place. So far all is commonplace, but the list contains, as would be supposed, some eccentricities. The refusal of a pension might easily suggest suicide to a severely logical mind, but it is passing strange that self-destruction should be chosen as a refuge from assassination, yet two such cases are recorded; while in one instance a source of trouble is assigned so utterly trivial as a *pimple on the nose!* But more striking, upon the whole, are the results brought out by classifying according to occupations. Strangely enough, farmers contribute by far the largest quota. Possibly the number is not disproportionate to the numerical strength of the farmer class in America—for these proportions are not worked out,—but it is singular to find them outnumbering the saloon-keepers, merchants, labourers, and clerks put together. Yet so it is. Among other classes, that of courtesans is sadly and suggestively conspicuous. For the rest, the list, though long and varied—for no condition is free from the occasional temptation to suicide,—contains nothing of special interest or in any way peculiarly noteworthy. The problem of the seasonal variation, however, appears likely to reward careful examination.

THE PHYSICALLY DETERIORATING INFLUENCES OF CIVILISATION.

AT the meeting of the Anthropological Institute on the 24th ult. (Mr. Francis Galton in the chair), Dr. George Harley, F.R.S., gave a discourse on the "Relative Recuperative Bodily Powers of Man living in a rude, and Man living in a highly civilised, state," in which he brought forward a number of hitherto unpublished, though mostly well known facts in support of his contention that the refining influences of civilisation had not been altogether an unalloyed boon. Cases were cited by the speaker in support of his view that, while man's physique as well as his mental powers had increased during his evolution from a barbaric condition into one of *bienséance* (his stature and his strength, as well as his length of days, having been increased *pari passu* with this improvement gradually), he has deteriorated in his bodily power, either to resist the lethal effects of injuries, or to recover from them as rapidly and as well as his less favoured barbaric ancestors. Nay, more: the cited illustrative cases showed it apparently to be a fact that all the appliances of civilised life which most potently minister to human comfort and human enjoyments have a deleterious enervating effect on the animal frame, as was demonstrated (said Dr. Harley), both by striking examples drawn from gipsy and tramp life, and also from domesticated animals, such as the sheep, the ox, the horse, and the dog, in all of which species high breeding was shown to conduce to a marked diminution in the bodily recuperative capacity. The speaker further maintained that man universally had naturally a high standard of bodily recuperative power inherent in his constitution, and that the present higher bodily recuperative capacity shown to be possessed by all men living in a rude state, whether in the form of savages, like the South African Kaffir or the North American Red Indian, or the gipsy or tramp wanderer among ourselves, arises from the fact that the refining influences of a higher civilisation materially diminish the animal recuperative capacity; and further that, although all men are of the same flesh and blood, their different modes of life and different social habits have induced in them very varied degrees of nerve sensibility, as well as of recuperative bodily power.

EXTREMES OF TEMPERATURE.

IT is not without cause that Englishmen so ceaselessly grumble at the weather. There is no stability, no moderation about our climate. It is either very cold or very hot; or if the general atmosphere be fairly comfortable the bitter north-east wind makes us miserable. At this moment the delicate have barely recovered from the sufferings inflicted upon them by a cruel season, which had no legitimate claims to be called Spring, when they are assailed with the plague of summer heat. There is really no rest or peace for any save the strongest in this "tight" but ungenial "little island" of ours. It is vain to preach caution. How can the most careful of mortals avoid draughts when the ordinary temperature in-doors is between 70° and 80° F.? Windows must be thrown open, and the air will rush in, which is relatively, if not absolutely, of such lower temperature as to give the sensation and do the deadly work of cold draughts. So with clothing. In the sweltering heat it is impossible to wear wraps which are nevertheless necessary to protect the susceptible from those currents of air that rush up side streets and round corners. If, regardless of comfort, the weakly consent to endure these wraps, they cannot do more than in a very moderate way defend themselves against exceptional perils. Perhaps the wisest — certainly the happiest—are those who have never, by pampering their susceptibility, rendered themselves the creatures of conditions in the presence of which it seems impossible to be either contented or safe.

SANITARY WORK IN PETERBOROUGH.

A REPORT which was presented to the Town Council of this city by the inspector of nuisances in March last shows a very discreditable state of things as regards refuse removal. We are informed that house refuse is periodically removed from 332 houses in a city which in 1881 had a population of 21,212, and it is added that great difficulty is experienced with occupiers of small tenements who allow their ashpits to be filled to overflowing before they will have them emptied. We are bound to infer that the inspector is here speaking of houses other than the 332 as to which periodic removal is in force; and we can only wonder what else could be expected than the grave result which he deplores, and which ensues "in the thickly populated and poorer parts of the borough." It is a primary duty of a sanitary authority to see that such refuse is periodically removed from the neighbourhood of all dwellings within their jurisdiction, and this at very short intervals. Occupiers should never be held to have a voice in determining the frequency of such removal unless they have a piece of garden ground on which such refuse can be properly deposited at least once in every week. Where, as in Peterborough, this is not possible, it is the obvious duty of the

Digitized by Google

sanitary authority to undertake this duty themselves; and it should be remembered that it is precisely the poor (who can neither pay nor arrange for the frequent visit of a scavenger, and who prefer to wait until there is a good load of stuff to remove) who most need the intervention of the authority in such a matter. Whatever the system or want of system is that prevails in Peterborough, it is evidently one that favours the retention in the vicinity of dwellings of the very materials which a sanitary authority should aim at getting rid of at the shortest practicable periods.

COCAINE AND ITS USE AS A LOCAL ANÆSTHETIC IN DENTAL SURGERY.

COCAINE having now taken a place in the Dental Pharmacopœia for various uses, it was desirable that some *résumé* of the literature of the subject, especially with reference to the injection of the drug for producing anæsthesia, should be made, and Messrs. Cunningham and Hern are to be congratulated upon the exhaustive character of their respective communications to the Odontological Society. Both papers cover much the same ground, and the conclusions arrived at are very similar. With regard to the physiological action of cocaine, much experimental research has been performed by von Anrep, Mays, Biggs, Hughes Bennett, and others; and although the results recorded are not quite uniform, yet these discrepancies are readily explained by the different methods of investigation, and the varying degree of susceptibility to the drug of the individual animal or person. Generally, it may be concluded that cocaine produces the following effects:—On respiration it first increases the number of respirations, then decreases them; in larger doses death ensues from paralysis of respiration. On the heart it has a depressant action, reducing the force and frequency of the pulsation, finally arresting the auricles and ventricles in diastole. In small and large doses it produces at first constriction of the blood-vessels, with a rise of blood pressure, succeeded by a considerable fall. Locally applied, cocaine also produces contraction of the small arteries. On the nervous system, small doses increase the reflex irritability of the cord; large doses reduce it considerably. On nerves, small doses heighten the irritability of the sensory fibres, but exert no effect on the motor fibres; larger doses completely paralyse sensory filaments and greatly diminish the irritability of motor. Salivary secretion is markedly deficient in many, and the temperature raised in some cases. A careful examination of the very large number of cases of cocaine injection now collected has led both Mr. George Cunningham and Mr. Hern to express very much the same views, which we quote in the latter's words, "In judging of the practicability of the employment of cocaine as an anæsthetic for extractions, one has to weigh the advantages and disadvantages of its employment, and compare it with those agents for the production of general anæsthesia now in use. After doing so, I am led to the following conclusion—viz., that as an agent for general use in extraction: 1. The physical barrier to injection which the bony alveolus interposes. 2. The pain, however slight, due to the puncture of the syringe. 3. The mental suspense due to the necessity of waiting several minutes between the injection and operation. 4. The full consciousness under which the operation is performed. 5. The varying idiosyncrasy of patients with reference to the drug. 6. The inconstancy of production of complete anæsthesia. 7. The necessity of limiting the dose, so that only one part of the mouth can be safely anæsthetised for the same patient at a given time, and that only such as to allow of one, or at most two, teeth being removed. These all combine to relegate the drug to a subordinate and secondary position, leaving nitrous oxide in the possession of the field as *facile princeps* for the vast majority of such operations. Other than for extraction there are various operations in which cocaine can be beneficially employed."

THE HEALTH OF THE CROWN PRINCE OF GERMANY.

ON Wednesday, June 8th, Dr. Morell Mackenzie, in the presence of the Crown Princess and Dr. W. Wegner, removed a second piece from the growth in the left vocal cord of His Imperial Highness. At a consultation held the following Friday Professor Virchow read a most fully detailed report of his examination of the growth, which he described as a "pachydermia verrucosa." He stated that the portion submitted to him showed a great increase in the number and size of the epithelial cells, some of which were empty, whilst others contained colloid matter, also that the papillæ were larger and more numerous than in normal mucous membrane. Numerous bloodvessels and nerves were found in the growth, but we believe no morbid products were present in the submucous areolar tissue. Professor Virchow gave a most favourable prognosis. In view of Professor Virchow's statement there is reason to hope that the Crown Prince will in time be entirely cured, though it must not be forgotten that recurrence is a characteristic feature of these papillary growths. At the urgent request of Dr. Mackenzie the Crown Prince has ordered a detailed report of Professor Virchow's examination to be published, and Dr. Virchow has informed us that this report will appear in full in this week's issue of the *Berliner Klinische Wochenschrift*.

DEATH FROM OVERCROWDING.

ALTHOUGH overcrowding is pretty general in manufacturing towns, we seldom hear of a death from this cause. A case has been recently investigated by Mr. Rowbottom, the coroner for Wigan. It transpired at the inquest that the deceased, a young man of twenty-two years of age, was a labourer at some ironworks in the neighbourhood, and retired to rest on the night of the 6th inst. in his usual health. He was called early next morning to go to his work, but stated he would not go that day. The other occupants of the room (lodgers) went to their work, and he was left alone. At 9.30 A.M. he complained to the landlady that his throat was sore, and she applied a poultice. At 12.30 noon she sent for Dr. Brady, who at once went to the man, and found the atmosphere of the room in which he was overpowering. The window was opened, and, after examining the man, he came to the conclusion that he was suffering from the effects of mephitic gases; his throat was of an intense purple colour, the neck slightly swollen, his general appearance indicated inefficient aeration of blood, and there were spasms at times of laryngismus stridulus. Dr. Brady gave directions as to treatment and left the house. The man died shortly afterwards. He made an attempt to vomit, fell back in bed, and died as if choking. Dr. Brady refused a certificate and communicated with the coroner, desiring a second medical man at the post-mortem. The coroner ordered a post-mortem, and asked Mr. Berry to be present with Dr. Brady. The post-mortem appearances were those of poisoning by carbonic acid gas. The trachea was intensely congested, as were also the bronchial tubes. The right side of the heart was filled with very dark fluid blood; the lungs and kidneys were congested, and dark in colour. The mucous coat of the stomach was in appearance as if stained with port wine lees. All the organs were healthy, with the exception of this venous congestion. There was nothing else to account for death. It was shown at the inquest that in this house, with two rooms above and two below (and these small rooms), eleven persons lived—a man, his wife, five children, and

Digitized by Google

four grown-up men lodgers. In the room in which Dr. Brady saw the man on his visit, were three beds. The room was 7 ft. high, and 10 ft. 9 in. by 11 ft. 8 in.: making allowances for recesses, and deducting space occupied by furniture, a cubic space of 842 ft. Seven persons had slept in the room, but the belief was that a larger number occupied it. The landlady stated that the deceased had slept in the adjoining room, which was a little less in cubic space, and contained two beds for the lodgers. The jury found a verdict that the deceased died from asphyxia caused by overcrowding. In manufacturing towns like Wigan persons occupy houses and take in lodgers, but, not having these registered, they evade the Lodging Houses Act, and thus escape inspection. The sanitary authority, however, should strive to get houses like this one under its control.

THE NATURAL HISTORY OF WELL WATERS.

ANOTHER important contribution to science comes to us from the celebrated laboratory and experimental farm at Rothamsted. Sir J. B. Lawes and Dr. Gilbert, whose labours, spread over a long period of time, have done so much for agricultural chemistry, did wisely when a few years ago they took Mr. Robert Warington into their scientific partnership. The present research stands in the name of the younger worker only, although he carries on the work and has doubtless been aided by the counsel of his distinguished *confrères*. Mr. Warington's paper occupies more than fifty pages of the current number of the journal of the Chemical Society. It will be studied by all interested in sanitation or scientific agriculture, and it contains such a mass of facts and tables that it is not possible to give any adequate idea of it in a narrow compass. Moreover, there are as yet no great generalisations to record, but chiefly a mass of statistical evidence which grows more detailed and accurate, and therefore more valuable, every year. Fair inductive reasoning is, however, applied to the facts. The first section deals with the rain water of Rothamsted, which has been systematically collected and measured since 1853, and which is evidently the basis of the whole inquiry. The average proportion in one million parts of this water is of chlorine 2·01, of sulphuric acid (SO_3) 2·52, of ammonia 0·35, and of total combined nitrogen 0·67. The last item is equal to about 4·4 lb. per acre per annum. Then comes a consideration of the drainage water. Ever since 1870 several isolated patches of prepared soil, consisting of loam and flint resting on a clay subsoil, supported on perforated iron plates and protected laterally by impervious walls, have been kept free from vegetation and manure. The beds are respectively twenty, forty, and sixty inches thick, and the drainage water is collected, measured, and analysed. The thickness of the bed was found to make no important difference, and the results on the five-feet bed are taken as typical. Of 31·04 inches of rain which fell on this soil, 17·09 inches evaporated and 13·95 inches percolated below five feet. In the drainage water the chlorine was found to be the same as in the rain water, but concentrated by the evaporation; while the nitrogen, as nitrates, was on the average 10·7 per million—the process of nitrification being most active during summer, while the principal discharge of nitrates was during autumn. The influence of vegetation is next studied. The conditions at Rothamsted are remarkably suitable for experiment. One celebrated field has grown wheat continuously since 1843, and one portion of it has never been manured. The drainage water from each is carefully collected, measured, and analysed. Vegetation, especially during its active stage, increases enormously the surface evaporation by transpiration of water through the plant, and in our climate during summer drainage is entirely suspended by the action of a vigorous crop. Interesting details are given as to the quantity and composition of the drainage water at various seasons of the year, especially with reference to the process of nitrification and the absorption of nitrogen by growing crops. As to evaporation, the results seem to show that, in round numbers, about one-half the rainfall of the year percolates through bare soil, and about one-third through unmanured soil cropped with wheat. This, of course, is only true under the conditions prevailing at Rothamsted. Armed with these valuable factors, Mr. Warrington has, with laborious skill, investigated the well waters of the neighbouring village of Harpenden—some of which are uncontaminated, while others are certainly contaminated. We must refer to the original paper for the very interesting observations which the author has made upon these works and their apparently eccentric contamination. He does not profess to explain all the anomalies, but, knowing and using as a basis the composition of the uncontaminated waters of the district, he has been able to throw light upon some of them. The effect of season, variation of rainfall, and local circumstances upon the composition of the well waters is amply illustrated, and the large quantities of calcium, magnesium, and sulphuric acid in the polluted waters is both interesting and important. From the whole study we gather the general inference, by no means new to the experienced chemist, that it is very unsafe to give a definite opinion on the quality of a water without a greater knowledge of its source than can be gained by a mere analysis. The analysis is essential, but it can only be interpreted by what in medical practice is known as the family history of the case.

PROF. GAYET ON OPHTHALMIA NEONATORUM.

DR. GAYET, Professor of Ophthalmic Surgery in Lyons, urges his pupils, in a clinical lecture on Ophthalmia Neonatorum, published in *La Province Médicale*, to search diligently for the gonococcus of blenorrhagia in all cases of ophthalmia occurring in very young infants. It does not, he says, require any extraordinary skill, and can be accomplished in as short a time as the ordinary examination of urine for albumen. A particle of the pus is placed on a glass slide and spread out by means of a second slide; the two are then separated, furnishing two preparations. They are stained by dropping a mixture of an alcoholic solution of methyl blue with an equal volume of water on them, allowing it to remain for two minutes. They are then washed with plenty of water. On microscopic examination each of the leucocytes will be seen to have two, three, or four nuclei, this being a special character of the disease, the increase in the number of nuclei heralding the approach of the gonococci, which will be observed as intensely blue spherical bodies in the interior of some of the leucocytes. If only one leucocyte so invaded is discovered, the diagnosis of blenorrhagic inflammation is rendered certain. With regard to treatment, the child must be watched "like milk on the fire," the visits being more than one per diem. Three indications present themselves: 1. To clear away the agent of infection. 2. To prevent its development. 3. To destroy it where it is. To fulfil the first, frequent and careful washing out is requisite. The eyelids should be everted, the mucous membrane stretched, and all the folds of the conjunctival sac thoroughly syringed out with a ball syringe; the eyelids should then be replaced, well rubbed on the outside, again everted, and the syringing repeated. In this way all the pus will be removed, but it is a somewhat difficult and tedious operation. In order to destroy the microbes which have already penetrated into the substance of the conjunctival mucous membrane, they must be pursued and attacked by the solid mitigated nitrate of silver, a solution of common salt being afterwards employed to neutralise any superabundance of caustic. The

Digitized by Google

mother should be directed to wash the eyes with a solution of corrosive sublimate (1 to 6000), and to keep small compresses wet with iced water on them. When the disease appears to be cured it is necessary to be on the look-out for a return; the microscope should therefore be in constant requisition in order to detect microbes, even after all apparent discharge has ceased. The most favoured prophylatic measure by Dr. Gayet is the employment of a vaginal douche with a 1 to 6000 corrosive sublimate solution at the commencement of all labours, especially when the woman suffers from leucorrhœa, in which case the child should not be allowed to remain too long in the passage.

THE NATIONAL MEDICAL CONGRESS OF ITALY.

OUR Rome correspondent writes:—"The Italians are possibly 'over-doing it' in the matter of congresses, but considering how jealously public meeting used to be restricted even on purely scientific subjects, the error is a venial one and quite on the right side. On the 1st inst. the National Medical Congress opened its sittings here in the great hall of the Senatorial Palace in the Capitol. Three hundred medical men from all parts of the peninsula were present, and on the presidential platform Signor Crispi, Minister of the Interior, represented the Government, the Duke Torlonia the Municipality, and a number of well-known physicians and surgeons the various medico-chirurgical associations of the city and provinces. The feature of interest was the eloquent speech of Crispi, who claimed a more than official—a personal—interest in the Sanitary Code of the late Dr. Bertani, brought before Parliament by the Prime Minister, Depretis. Bertani, the surgeon-in-chief of Garibaldi's patriotic campaigns, whose premature decease some thirteen months ago was commented on in THE LANCET, abandoned a brilliant academic and civic career to minister to the wounded red-shirts, and after their common goal was won devoted himself heart and soul to a department of medicine comparatively unfamiliar to him—public health—that he might render physically and morally sound and strong the national life he had helped to unify. Crispi's *éloge* of his friend was in his happiest vein, and seemed to infuse a genial spirit into the more formal speeches that came after. The programme of the Congress, an extensive one, in harmony with the sentence of Cicero, inscribed in imposing characters over the entrance-portal, "Hominum Vitæ et Saluti Consulendum," will doubtless give occasion to discussions of interest, not only for Italian medicine, but for that of other States."

EARLY DIAGNOSIS OF PHTHISIS.

As an original contribution to the *Revue Internationale des Sciences Médicales*, No. 5, Dr. E. Martel writes on the early diagnosis of pulmonary phthisis by an examination of the larynx. We cordially concur in the statement that to diagnose pulmonary tuberculosis as soon as possible is of the highest importance in the treatment of this affection, but far more evidence than has yet been adduced will be required to sustain M. Martel's principal proposition, to the effect that a "paralysis or a paresis of a vocal cord, with or without derangement of phonation, indicates in nearly all cases an incipient pulmonary phthisis." In other words, the discovery of an imperfection in the action of one vocal cord is equivalent to proving that the patient so affected will eventually develop unmistakable signs of phthisis, and this, too, in the lung of the same side as the impaired vocal cord. The impairment of the action of the vocal cord may precede the development of physical or other certain signs of phthisis, even by as long a period as four years. M. Martel's own words may be quoted, as they are so very remarkable and emphatic: "I have always examined the larynx even when there were no signs pointing to mischief therein, and I have been surprised at the number of 'lame' vocal cords which it has been my lot to examine; but we ought not to say, as soon as the discovery of a weakened vocal cord is made, that the apex of the left lung will become tubercular in a nearer or more remote future; there are exceptions, and aneurysm of the aorta, tracheo-bronchial adenopathy, and tumours of the neck may lead to functional troubles of the vocal organ." Nevertheless, in the next paragraph, M. Martel avers that in all cases of examination of the thorax or neck we shall find the cause of the vocal paresis; whilst in incipient phthisis the lung will appear to be healthy to physical examination of all kinds, and yet the lameness of the vocal cord alone will suffice for us to assert that something abnormal is taking place on the same side of the respiratory apparatus (lung).

MEANS OF ISOLATION AT SALFORD.

IN view of the contemplated purchase by a railway company of the existing infectious hospital for Salford, Dr. Tatham has submitted to his sanitary authority an able and exhaustive report on the principles which should govern them in the provision of a new hospital. Care has been taken to study the whole subject, and Dr. Tatham has interviewed the departments of the Local Government Board in order to elicit from them any expression of opinion formed since the last official publications were made on the subject. As a result of these steps, Dr. Tatham recommends that 200 beds—at the rate of one bed per 1000 inhabitants—should be provided as the permanent accommodation for the borough, and he enters into details as to the plan on which these should be arranged in different pavilions. The subject of the isolation of small-pox patients in urban communities is for the moment not dealt with, because the Monsall Hospital, affiliated to the Manchester Royal Infirmary, is available for the reception of cases of that disease. But this, it is admitted, is not likely to be a lasting arrangement; and when it comes to an end this very difficult problem will have to be faced in Salford. Dr. Tatham's report is so complete that its perusal would well repay those authorities and officers who have the provision of infectious hospital accommodation in contemplation.

ACUTE INFECTIOUS MYOSITIS.

THE subject of myositis which Mr. Treves brought under the notice of the Clinical Society last year has been further illustrated in a paper read by Dr. Jackson at a recent meeting of the Massachusetts Medical Society.[1] The case was that of a woman aged thirty-six, who had been seen by Dr. Jackson when in Strasburg. The illness began with malaise, sore throat, and a red papular eruption on the face, which disappeared in a week's time. Then occurred swelling, accompanied by pain, in the shoulders, legs, and sacral region. There was moderate fever, except at the close, when the temperature was high and pneumonia occurred. There was slight œdema of the face and extremities, the muscles of the limbs being fixed and rigid, extension causing pain. There was paresis of the soft palate, diminished electrical reaction, and absence of reflexes. The patient died a week after admission. Professor Kussmaul, who had charge of the case, diagnosed a diffused myositis, and said the case reminded him clinically of one in which thousands of miliary aneurysms were found all over the body. Trichinosis was at first thought of, but was eliminated by the history and the absence of gastro-intestinal prodromata. The post-mortem examination was made by Professor von Recklinghausen, and it was found that the muscles throughout the body, especially in the extremities, the trunk, and the face, were pale and moist, many had small hæmorrhages

[1] Boston Medical and Surgical Journal, 1887, No. 21.

Digitized by Google

in their sheaths, whilst their fibres were waxy and granular, and the interstitial tissue was infiltrated with round cells. In the discussion on the paper, Dr. Fitz remarked on the liability of the muscles to participate in infective processes, and suggested that in the case related by Dr. Jackson diphtheria may have been the primary source of the infective inflammation.

AMBULANCE ARRANGEMENTS FOR THE JUBILEE PROCESSION.

WE are glad to be able to state that Colonel Sir Charles Warren, Commissioner of Police of the Metropolis, in view of the probability of accidents which must necessarily occur on an occasion when large masses of people are gathered together, and of the possibility of cases such as sunstroke, syncope, &c., due to the present sultry weather, has taken the precaution of arranging with the Chief Surgeon of the Metropolitan Police for ambulances to be stationed at various points along the route over which the procession will pass. The actual stations of such ambulances will be notified in the police orders. We further understand that in addition to those possessed by the police a certain number of ambulance vehicles will be supplied by the Order of St. John of Jerusalem, and that if the permission of the General Commanding the Home District be obtained the services of the various companies of the Volunteer Medical Staff Corps will be available at their respective hospitals or at any point along the route where their presence may be deemed desirable. It may be interesting to add that in the ranks of the police are a large number of men who have previously served in the Army Hospital Corps, and who have been therefore selected for special duty on this occasion.

THE LOCAL DISTRIBUTION OF PHTHISICAL LESIONS.

IN a memoir upon the pathology of pulmonary diseases (*Zeitschrift f. Klin. Med.*, abstracted by Sahli in *Fortschritte der Medicin*, No. 11, 1887), Dr. A. Hanau suggests that the reason for the preference of the apex of the lung for the initial lesion of phthisis is to be found in the comparatively weaker expiratory power of this part of the organ. In support of this he cites the frequency with which anthracotic and chalicotic processes are to be met with at the apex or a short distance below, corresponding to the sites of tubercular foci. Being unsupported, the apex of the lung can be fully expanded by inspiration, but it is less under the influence of expiratory forces than the lower parts of the lung. As a consequence, in forced breathing the air is very likely to stagnate in the apex; and, as Mendelsohn showed with respect to emphysema, there may even be a reflux of air from the normally acting lower parts of the lung into the upper. The comparative immunity from tubercular phthisis enjoyed by the subjects of spinal curvature, by those whose lungs have become cirrhotic, as coal miners, or the emphysematous, may in each case be attributed to defective power of inspiration possessed by the apex or the whole lung in such conditions. The selection of the middle lobe and lower part of the upper lobe for the occurrence of secondary foci due to the aspiration of the contents of cavities which have escaped into the bronchi is also explained. Usually the areas of broncho-pneumonia arising from aspiration of noxious matter are to be found in the lower and posterior parts of the lung. This is due to the dorsal decubitus of most of the patients in whom this complication supervenes. But it is otherwise in phthisis when the subject is not confined to bed, for the regions next to be involved to the apex, and infected secondarily from it by means of aspiration, are the middle lobe and contiguous part of the upper lobe. These regions are the most liable to be fully distended in coughing, and the products of the apical vomicæ will be more readily pressed in their direction by the backward current of air. Hanau also ascribes the frequently rapid extension of phthisis in women after childbirth to the aspiration of the contents of cavities into previously healthy parts of the lungs following on the extraordinary respiratory efforts made during parturition. Aspiration as a factor in the dissemination of tubercular lesions is not perhaps as fully recognised as it should be, but it certainly serves to explain the matter in a plausible way, and is in absolute harmony with the doctrine of the local infectivity of tubercular products, which is so admirably illustrated in the distribution of the lesions of uro-genital tuberculosis.

THE MATHEMATICAL TRIPOS, 1887.

THE list of Mathematical Honours for the current year exhibits some rather interesting features. In the first place, it is remarkable that four names are bracketed together for the post of "senior" in the Tripos, Trinity and St. John's equally dividing the honour. Of the thirty wranglers, Trinity claims nine; St. John's and Christ's, four; King's College, three; Emanuel, Pembroke, and Sidney, two each; whilst Peterhouse, Jesus, Corpus, and Queen's each supply a single wrangler. Caius College, which in former days furnished so many senior wranglers, and nearly always had a candidate high up in the list, this year supplies no wrangler. It would be interesting to inquire whether this decline in the mathematical honour list is exceptional and due to accidental causes or to failure in drawing mathematic talent to the College. Caius College has been the foremost in providing handsomely for the requirements of natural science teaching, and its success in that direction has been very marked; it is just possible, therefore, that some of its best scholars have been attracted in that direction, and have sought for honours in the Natural Science instead of the Mathematical Tripos. If such should prove to be the case, we may regard the present decline of this, as it might almost be called, Medical College as regards its position in the Mathematical Tripos with equanimity, and indeed with satisfaction, as showing that the medical profession is attracting some of the best intellect at the College to the scientific training necessary for its successful cultivation. Among the successful Colleges this year in the Tripos, Christ's certainly deserves the palm; though considerably smaller than St. John's College, it furnishes an equal number of wranglers, three of whom are in the first thirteen. This, again, is another instance of a change of tradition, since in former years Christ's was regarded more as a classical than a mathematical college.

FREE LIBRARIES AND CONTAGION.

No public institution is so fortunate as not to be liable to misuse. It is not, therefore, to be wondered at that the free library, notwithstanding the benefits it undoubtedly confers, has been found to have its disadvantages. A complaint has been laid against it that it may, and sometimes does, become the means of carrying infection. A correspondent, writing a few days ago, quotes what seems to have been a case directly in point. A child obtained from the library a book which had just come from a house in which there was scarlet fever, and two days later was taken ill with this disease. The period of incubation in scarlatina is somewhat variable, but it is not incompatible with the view that the book was here the medium of infection. Whether the disease could not have been traced to any other possible source is uncertain, but, at all events, this case indicates a danger which appears to be inseparable from the free library system. The only possible safeguards are to be

Digitized by Google

found—firstly, in a compulsory notification of infectious disease to the librarian, and secondly, the subjection of every returned book about which there is any doubt on the score of contagion to a process of disinfective fumigation. In this connexion reference may be made to an incident recorded in a Russian periodical. Typhus fever has recently been very prevalent in Sebastopol, and it is stated that its ravages were to some extent controlled by the judicious action of the librarian of the town library, who appealed earnestly to the subscribers to cease temporarily from changing books in case of the fever appearing in their respective families. In this way the frequenters of the library and the readers of the books lent out, as well as the staff of servants and librarians, have been saved from infection.

A NEW AND IMPERVIOUS DRESSING.

PHOTOXYLIN, a substance in use amongst photographers, was recommended some time ago by Dr. Krysinski as a suitable material for mounting microscopic specimens, and more recently still it has been utilised by Prof. Wahl of St. Petersburg as a substitute for collodion in surgical practice. A 5 per cent. solution in equal parts of alcohol and ether he finds preferable to collodion, as it adheres more firmly to the skin, not being so easily rubbed off in washing. It is absolutely impervious to liquids, and exerts a perfectly even compression on the tissues. In out-patient practice Prof. Wahl finds that, after small operations such as the extirpation of glands, the application of photoxylin solution enables him to dispense entirely with voluminous antiseptic dressings; also in plastic operations on the face, and in operations in the neighbourhood of the male congenital organs, such as those for the radical cure of hernia and castration, where it is very difficult to prevent the urine soaking through antiseptic dressings. Prof. Wahl, after carefully arresting all hæmorrhage, closes the wound with sutures and gelatine plaster, and then covers the whole with a thin layer of wool soaked in a solution of photoxylin. This, it is stated, will remain eight or ten days, entirely resisting all the effects of moisture. Even in laparotomy, extensive dressings may, he believes, be dispensed with by painting a solution of photoxylin over the wound with a brush, or by the application of a layer of cotton wool soaked in the same liquid. Photoxylin appears to be unknown in this country. It was introduced by Messrs. Mann of St. Petersburg.

THE NEWINGTON MEDICAL OFFICER OF HEALTH.

WE regret the action which has been taken by the Newington vestry in connexion with the office of medical officer of health, which has become vacant by the death of Dr. Iliff. The bye-laws of the vestry are specially contrived to prevent vestrymen from taking paid offices, and to secure the election of the best available persons. Thus, "no vestryman shall be eligible for nomination or election to any paid office or place under the vestry, and no person shall be nominated or elected to any such paid office within six months after he shall have held the office of vestryman." And further, the mode of election by selection from amongst candidates is provided for. In the face of this the resignation of Mr. G. Millson, L.R.C.P., a vestryman, was accepted at the first vestry meeting after Dr. Iliff's death; Mr. Millson's offer "to discharge the duties of medical officer of health gratuitously until such time as the vestry see fit to elect a permanent officer" was accepted; and it was decided "that the appointment be reviewed"—not made—"at the expiration of six months." In our judgment nothing could have been contrived which would more completely frustrate the intention of the bye-laws than the steps which have been taken.

REG. v. THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

WE publish in another column an important judgment delivered in the Queen's Bench Division in regard to the power of the Medical Council to remove the name of dentists from the Dentists' Register in cases in which the qualifications on the strength of which registration had been effected had been withdrawn by the medical authorities granting the said qualifications. The questions raised by this decision are so important, and the report reaches us so late, that we defer comment till next week. It will be seen that judgment is given in favour of Mr. Partridge, who held a diploma in dentistry from the Royal College of Surgeons of Ireland, which was withdrawn on account, as alleged, of his advertising to attract business. The Council, without an independent examination of the facts, merely on the ground of its duty to keep a correct Register, erased his name. The mandamus, on application on behalf of the Medical Council, will not be drawn up for a week.

DRINKING TROUGHS AND GLANDERS.

AT a recent meeting of the Commission of Sewers, the Streets Committee advised the non-erection of a drinking trough in Farringdon-street on the ground that it was likely to serve as a means of disseminating glanders. This is a serious indictment, and it is said to be supported by the observations of several veterinary surgeons. It would be interesting to learn on what precise statistics it is founded, and the mere assertion made on such authority justifies an inquiry into the subject. In consideration of the undoubted benefit which these troughs confer upon travelling cattle, the sufferings of which in hot weather would often without them be very great, it is to be hoped that the Commissioners will not accept the recommendation of their committee unless it is fully fortified by proof, but it would certainly be well for them to consider the alternative proposal made by one of their number, that the drinking trough should be so constructed that the water within it may be kept running, and thus be constantly renewed.

DEATH OF DR. OXLEY OF LIVERPOOL.

DR. MARTIN G. B. OXLEY, senior physician to the Liverpool Infirmary for Children, died at Llandudno shortly after midnight of the 13th inst. The deceased was a student of King's College, became M.R.C.S. Eng. in 1862, and later on M.K.Q.C.P.I. and M.B. St. And. Some years ago he suffered from mitral disease of the heart, for which he was attended by Dr. Glynn of Liverpool. He rallied from this, and after some months' rest resumed practice. But he had several relapses and recently went to Llandudno, where he hoped to benefit by the sea air and change. He was attended by Dr. Dalton, and it was hoped that he would recover. But a change for the worse occurred, and at 12.30 A.M. on the 14th inst. he expired. He leaves a widow and two sons to mourn their loss, as well as a large circle of professional and lay friends, among whom he was extremely popular.

FEVER AT STAPLEFORD.

STAPLEFORD, in Nottinghamshire, is under the jurisdiction and mismanagement of the Shardlow rural sanitary authority, and the Local Government Board having apparently failed to induce the authority to do away with the conditions periodically leading to fever prevalences in the place, have at last reminded them of the frequency with which the water supply has been condemned as dangerous, of the faulty system of midden-privies and the lack of drainage, and have finally thrown upon them the responsibility for

Digitized by Google

such further disease and mischief as may result. In such cases the Local Government Board have no power of enforcing the adoption of proper sanitary measures unless definite complaint is made to them of default under Section 299 of the Public Health Act, 1875. The matter must, therefore, now rest with those who elect the authority and reside in the district.

CONVERSAZIONE AT THE ROYAL COLLEGE OF SURGEONS.

A VERY successful conversazione was given by the President, Mr. W. S. Savory, F.R.C.S., at the Royal College of Surgeons on Wednesday evening last, nearly twelve hundred ladies and gentlemen being present, including a large number of nurses from St. Bartholomew's Hospital, whose dresses lent picturesque variety to a brilliant scene.

DR. DE GROOTE ON HOT CLIMATES.

IN a work on "The European in Hot Climates," recently published by a Belgian naval surgeon, Dr. de Groote, Central Africa in general and the Congo in particular are dealt with. With regard to the Congo, the author considers the climate more healthy than those of Brazil and the English and Dutch Indies. A good deal of practical valuable advice is given to travellers, emigrants, and colonists, for whom the work is mainly intended. The directions given for the immediate treatment of medical and surgical affections when out of the reach of professional aid will also prove valuable to this class of persons, and in the opinion of Dr. Thiriar, of Brussels, who has reviewed it in *La Clinique*, the amount of information given under this head is just what is required.

EUSTACHIAN OBSTRUCTION IN DIABETES.

WRITING in the *Revue Mensuelle de Laryngologie, &c.*, No. 6, on the troubles of hearing sometimes complained of by diabetics, M. Miot comes to the conclusion that the swelling, with œdema of the Eustachian tube, is a complication of diabetes which does not yield to ordinary treatment, but is amenable to the continuous current, which diminishes the congestion of the mucosa and allows of the introduction of bougies, as well as the employment of galvano-caustic agencies. The last-mentioned means appears to be the most efficacious and rapid method of restoring the functions of the canal.

HONORARY DEGREES OF DUBLIN.

IT is probable that several members of the British Medical Association will receive the degree of M.D., *honoris causâ*, at the hands of the University of Dublin on June 30th—Sir James Paget, Sir Spencer Wells, Mr. Simon, Professor Gairdner, and Dr. Edward Waters. It is intended to confer the degree of LL.D. on Prince Albert Victor on the same day.

THE PASTEUR COMMITTEE.

WE learn that the report of the Government Committee appointed to inquire into the efficacy of the Pasteur method is revised, and will be signed in a few days when sent round to the members of the committee. It will probably be in the hands of Mr. Ritchie by the end of the week, when he will, no doubt, lay it on the table of the House.

DEATHS OF EMINENT FOREIGN MEDICAL AND SCIENTIFIC MEN.

THE deaths of the following foreign medical and scientific men are announced:—M. le Dr. Rochas, General Secretary of the Rhone Medical Association.—Dr. L. K. Wagner of Kharkoff.

THE MEDICAL DEFENCE UNION.

THE Transactions of the Medical Defence Union are before us in pamphlet form, and give an account of the position of the Union in respect of membership and the action of the executive. The members amount to about 554. As regards action, some disappointment may be felt that it approaches so nearly to inaction. But this feeling will be modified on a careful perusal of the statement. For one thing, it seems quite candid and complete, telling the reader the various cases in which the action of the Union has been invoked, and the reply of the Union, with its reasons, which are generally sound and sensible. We do not think the worse of the Union for not proceeding heroically and sensationally, and it will take a stronger position if it acts slowly and wisely.

DR. GRAILY HEWITT.

AFTER twenty-two years of service, and in consequence of the pressure of private and other engagements, Dr. Graily Hewitt has resigned the chair of Obstetrics and Gynæcology in University College and his post of physician to the hospital. In accepting this resignation, the Council of the College passed a resolution expressing their high appreciation of the very eminent services which Dr. Hewitt has rendered to the College and hospital during the long period he has held the chair.

CONSULTATION FEES IN RURAL FRANCE.

THE bureau of the Haute Garonne Medical Association has been informed that sometimes a general practitioner calling in a consultant expects to be given a portion of his fee—in fact to receive a commission on the transaction, in the way in which commercial men remunerate others who introduce business to them. The bureau, being asked to express an opinion on this matter, had no hesitation in characterising any transaction of the kind amongst medical men as highly undignified. It added that the general practitioner is entitled to a consultation fee as much as the consultant, and that it would be a desirable practice to intimate this to the patient.

SIR FREDERICK ABEL.

WE regret to learn that Sir Frederick Abel, chemist to the War Department, has had an attack of double pneumonia. He is at present at Woolwich, and is considered by his medical attendant, the medical officer of the Arsenal, to be convalescent. The eminent chemist appears to have "caught a chill" while attending a public ceremonial.

GRANTS FOR SCIENTIFIC RESEARCH.

WE may remind our readers that the Scientific Grants Committee of the British Medical Association will shortly meet to consider applications for grants in aid of medical, surgical, and collateral research, to which purpose £300 is annually devoted. Applications should be forwarded to the office of the Association, 429, Strand, where particulars may be obtained of the conditions under which the grants are allotted.

HENLEY REGATTA.

WE have ascertained that, after all, there is as yet no new regulation in force to prevent the befouling of the London drinking-water supply by the house-boats that will gather together in such large numbers at Henley during the regatta week. The new bye-laws framed to prevent the contamination of the Thames still await the Royal assent. We shall deal more fully with this important question in our next issue.

Digitized by Google

SCARLATINAL KIDNEYS.

THE interesting contribution to the Pathological Anatomy and Histology of Scarlatina, appearing in the pages of the *Birmingham Medical Review*, from the pen of Dr. George Crook, whilst confirming the general truth of Klein's histological observations on the changes in the arteries and arterioles, states that the hyaline change is not met with so frequently or so well marked as Klein described. "Interstitial changes are undoubtedly rare in the first week, but in two cases their presence in the form of cellular infiltrations around the glomeruli, and in patches along the vessels in the labyrinth, could not be overlooked."

FOREIGN UNIVERSITY INTELLIGENCE.

Berlin.—Professor B. Fraenkel has just commenced work in his newly established University Policlinic for Nose and Throat Diseases.—Dr. Thorn, assistant medical officer of Professor Olshausen's University Gynæcological Clinic, has been appointed to succeed Dr. Hofmeier, who has gone to Giessen.

Buda-Pesth.—Professor Jos. Wagner, Director of the Second Medical Clinic, having held the professorship for forty years, is about to retire.

Dorpat.—Dr. Weil, Professor of Special Pathology and Therapeutics, who has been away during the winter endeavouring to recruit his health in the south, not having derived as much benefit as was anticipated from the climatic change, is now unfortunately obliged to relinquish all hope of returning to his work, and is therefore resigning his chair.

Kieff.—The medical library of the late Professor E. E. Miram has been presented to the University.

Prague (Bohemian University).—Dr. Karl Pawlik of Vienna has been appointed Professor of Midwifery and Gynæcology.

St. Petersburg.—Mdme. Auer, daughter of the late Dr. E. V. Pelikan, has given her father's valuable library to the Military Medical Academy.—Drs. Hertsenstein, Gendenreich, Cydakoff, and Sirotinin have been recognised as *privat-docenten.*

IT is officially announced that the Dean of Westminster has received the Queen's permission, and also the sanction of Her Majesty's First Commissioner of Works and of the Lord Chamberlain, to repeat the Jubilee service in the Abbey on Wednesday, 22nd inst., at 3 P.M. The service, which will include musical additions, will be held for the benefit of London hospitals. One third of the proceeds will be given to the Hospital Sunday Fund, which this year will lose the annual collection in the Abbey, one third to Westminster Hospital, and the remaining third will be divided between the Hospital Saturday Fund and the Western Dispensary. Tickets, at prices ranging from one pound to half-a-crown, will be issued by the Secretary of Westminster Hospital, to whom alone application should be made.

THE recent inquiry into the charges made against the Health Committee of the Manchester Corporation by the elective auditors has resulted in the finding that no charges of fraud have been sustained against any member of the committee or the committee's responsible officers, and that the shortcomings were no more than might be discovered in any other concern, public or private, of equal size.

AT a meeting of Convocation of the University of Oxford on the 9th inst. a grant of £100 a year for three years for the purpose of providing instruction in materia medica and pharmacy was carried by 38 votes to 19.

WE regret to announce the death of Mr. J. Beswick Perrin, M.R.C.S. E., of Leigh, Lancashire. Mr. Perrin was for some years Demonstrator of Anatomy in King's College, London, and afterwards at Owens College, Manchester, and will be remembered by many old friends and pupils as a most able dissector, an ardent anatomist, and an excellent teacher. After leaving Manchester, he settled in practice at Leigh, and soon became extremely popular and much respected in the district. In his earlier days he wrote many interesting and valuable anatomical papers in the *Medical Times and Gazette*, the *Journal of Anatomy and Physiology*, and the Transactions of the Zoological Society.

THE election of an Assistant Physician to the Royal Alexandra Hospital for Sick Children, Brighton, took place last week, there being six candidates, all of whom were highly qualified. Mr. W. C. Chaffey, M.B. Lond., late registrar to the Great Ormond-street Hospital, London, was elected by the Committee of Election, who had no personal knowledge of him; he was chosen purely on the ground of merit. The elections at this hospital being carried out by an Election Committee, canvassing either directly or through an agent disqualifies candidates.

THE borough of Oldham is about to receive a charter as a quarter sessions district, which will entail the appointment of a borough coroner. The only medical candidate is Dr. George Thomson, his opponents so far being all members of the legal profession. Our views of the question of medical coroners are well known, and we wish Dr. Thomson every success in his candidature.

ANOTHER outbreak of diphtheria has occurred on the Danish corvette *Dagmar*, which recently left Sheerness to resume her training cruise in the North Sea. The patients have been admitted by the naval authorities to the infectious wards of Melville Hospital, where three of the *Dagmar's* crew have been confined since the 29th ult.

AT the last meeting of the Royal Medical and Chirurgical Society, Professors W. H. Flower, Michael Foster, and Sir William Turner were elected Honorary Fellows, and Professors John S. Billings, Frederick Esmarch, and Richard von Volkmann, Foreign Honorary Fellows of the Society; Dr. S. J. Gee was elected Honorary Librarian.

THE Queen has been pleased to appoint James Patrick Tulloch, M.B., colonial surgeon for the Island of Tobago, to be an official member of the Legislative Council of that island.

A SEVERE epidemic of measles is raging at Winsford, Cheshire. The whole of the schools in the town are closed.

TESTIMONIAL TO MR. GODART.—It is proposed to present a testimonial to Mr. Godart upon the occasion of his departure for Sydney after thirty-seven years' service as pathological and anatomical draughtsman in the Medical School of St. Bartholomew's Hospital. A meeting will be held in the anatomical theatre on Saturday, July 2nd, at 1 P.M., to determine the form which the testimonial shall take. Subscriptions may be sent before that date to Mr. D'Arcy Power, Curator of the Museum, 26, Bloomsbury-square, W.C.

A PHYSICIAN ATTACKED BY ROBBERS IN HAVANA.—Dr. Vincente de la Guardia, a much-esteemed physician in Havana, was recently attacked and robbed in or near the city. He defended himself with vigour, but was unfortunately wounded

Pharmacology and Therapeutics.

TERTIARY ALCOHOLS.

DR. B. M. SHAPIROFF has made a number of observations on the physiological action of tertiary alcohols, and especially on that of dimethyl-ethyl-carbinol, a tertiary amyl alcohol obtained by the action of chloride of propionyl on zinc methyl. In its pure form this substance is a clear oily liquid with a strong odour. The melting point is 12° C.; the boiling point is 102·5° C.; and the specific gravity at 0° C., 0·828. On oxidation acetic and propionic acids are formed. When 0·001 to 0·005 gramme is injected under the skin of a frog, the first effect is to cause stupor—i.e., depression of the cerebrum; after which paralysis of the spinal cord is induced, evidenced by the arrest of the lymphatic hearts, the centres for which are, according to Veliki, located in the cord. No direct effect is produced on the hæmic circulation. In warm-blooded animals dimethyl-ethyl-carbinol diminishes the blood pressure, paralysing the vaso-motor centres, but does not exert any direct action on the heart. On the temperature it produces a decided effect, lowering it in a marked degree. The action of trimethyl-carbinol is very similar to that of the compound containing a molecule of ethyl, but less marked and slower. In general, according to the author, the tertiary alcohols, though they may have the same composition as primary alcohols, exert a very different physiological action, the latter class of bodies being general stimulants, while the former act as depressants.

Another Russian observer, Dr. Shumoboï-Simanovski has published some recent observations (*Ejenedélnaia Klinicheskaia Gazeta*, No. 11) on trimethyl-carbinol, which, he says, was obtained first by Butleroff by the action of zinc methyl on oxychloride of carbon, and also by its action on chloride of acetyl. It is sometimes described as tertiary pseudo butyl alcohol. As long ago as 1867 Danielevski reported at the first Congress of Russian Naturalists that this substance had the property of allaying irritability of the psychic centres without causing any preliminary excitement. Dr. Simanovski, from observations recently made on both warm- and cold-blooded animals as well as on patients, is now able to confirm the views of Danielevski, and also those of Thierfelder and Mering, who found that tertiary alcohols exerted a soporific effect on rabbits. The dose for an adult of trimethyl-carbinol is from ten to twenty drops. Given to two patients in Professor Botkin's wards suffering respectively from perinephritis and pleurisy, with a high degree of habitual and long-standing insomnia, it produced in both instances a really good night's sleep. There appeared to be no objection to repeating the draught on several successive nights.

ANTIPYRIN AND ACETANILIDE IN PHTHISIS.

IN comparing the effects of antipyrin and antifebrine or acetanilide in phthisis, Dr. Jablovski finds that acetanilide exerts a much more decided effect on the pyrexia. He remarks that by taking acetanilide such patients exhibit far less variation between the morning and evening body weight than under ordinary circumstances. The same is true with regard to antipyrin, but the effect is less marked. The loss by the skin and lungs is increased by antipyrin and very greatly diminished by acetanilide. Dr. Jablovski publishes a series of tabular results obtained during a long and painstaking investigation conducted upon patients in the Helsingfors Military Hospital.

HUAMANRIPA.

The plant known by the name of huamanripa amongst the natives of Peru is made use of by them in cases of bronchitis, catarrh, and slight hæmorrhages. It has been recently examined by Dr. Zapater, who employed an infusion made of 25 parts of the leaves to 1000 of water. In small doses it quickens the cardiac pulsations and augments the secretions, especially the saliva. In larger doses it produces vomiting and sweating, and diminishes the cardiac beats, the respiration, and the temperature. In cases of pleurisy and pneumonia it appears to exercise almost a specific action. It is, besides, an excellent sudorific.

A DEMONSTRATION of amalgamated temperance societies took place on the 12th inst. in aid of the North London Nursing Association.

THE HOSPITAL SUNDAY FUND.

ON the 11th inst. the sixth of the fourteen public meetings to be held in support of the Hospital Sunday Fund was held in the Shoreditch Town Hall. The chair was taken by the Bishop of Bedford, supported by the Marquis of Lorne, Mr. J. Bigwood, M.P., Sir Sydney Waterlow, Sir Edmund Hay Currie, the Rev. Septimus Buss (vicar of Shoreditch), the Rev. Prebendary Billing (rector of Spitalfields), the Rev. W. Cuff, and others. The following is a list of the institutions comprised in the Shoreditch district which benefit from the Hospital Sunday Fund:—City of London Hospital for Diseases of the Chest, German Hospital, North-Eastern Hospital for Children, Poplar Hospital, East London Hospital, Metropolitan Free Hospital, London Dispensaries, and City of London Lying-in Hospital. The expenditure and liabilities of these institutions in 1886 exceeded the income by £30,000. The Chairman, in opening the proceedings, said that if there was one charity which more than another was free from the danger of doing more harm than good it was the Hospital Sunday Fund. At present, however, neither the supply of hospitals nor the support of those existing was, in his opinion, sufficient. He should be very sorry if the hospitals had to become a department of the State or to be supported out of the rates, but if the necessary funds were not otherwise provided they might come to that. Centralisation of management was never very efficient, and the hospitals would suffer very greatly from it; besides, the public would be robbed of one of the most healthy and pure channels of benevolence that were open. The Marquis of Lorne moved the first resolution—"That this meeting pledges itself to use every endeavour to arouse the inhabitants of this district of London to the importance of maintaining the hospitals and medical charities in the utmost efficiency. In furtherance of this object it urges the clergy and the ministers of religion to point out the advantage of giving through the Hospital Sunday Fund, owing to the nominal cost of so collecting funds for the hospitals, and to make an earnest appeal to the people to so increase their contributions as to secure that the whole sum collected shall not be less than £100,000." He said that the grave condition of the hospitals' finances ought not to be allowed to continue. In the East-end, and the more densely populated districts of London, medical and surgical aid should be near at hand, and every well-considered attempt to provide more extensive accommodation in these crowded districts ought to be welcomed. The Rev. S. Buss seconded the resolution, which was unanimously carried. Sir Sidney Waterlow then moved the second resolution—"That this meeting regrets to learn that the expenditure and liabilities of the hospitals and medical charities of this district in the year 1886 exceeded the income by £100,000, and pledges itself to increased exertion, with a view of preventing any like deficiency during the current year." He said that the public of the metropolis did not fully comprehend the duty and responsibility which rested upon everyone of maintaining the hospitals in a state of efficiency to relieve the sick poor. As chairman of the Distribution Fund, he could assure the public that the money contributed to the fund went directly, with the smallest possible deductions, to the objects for which it was intended, the management, collection, and distribution of the fund only costing 3 per cent. The Rev. Prebendary Billing having seconded the resolution, it was carried with only one dissentient. The Rev. W. Cuff then proposed a vote of thanks to the Bishop of Bedford for presiding, and to the Marquis of Lorne for his attendance. Sir Edmund Hay Currie, in seconding the resolution, said he wished to disabuse people of the idea that the money being asked for was for the establishment of new hospitals, though these were needed badly enough. The existing hospitals were not doing anything like the work they might do simply because they had not enough funds, and the money asked for was to carry them on efficiently; £40,000 was collected on Hospital Sunday, and though this might sound a large sum, it was perfectly unworthy of such a great city as London, for it did not amount to £15 for every place of worship. The resolution was carried by acclamation, and the proceedings came to a close.

On the 13th inst. a meeting was held at St. Mary's, Newington, Parochial Hall, Kennington Park-road. The Newington district includes all London south of the Thames

Digitized by Google

and contains nine hospitals and eleven dispensaries participating in the fund. During 1886 these institutions accommodated 7594 in-patients and relieved 92,025 out-patients, and in the same year their total income was £41,349, while their expenditure amounted to £44,190. The chair was taken by Sir Wm. Plowden, M.P., who was supported by the Rev. C. H. Spurgeon, the Rev. G. T. Palmer, the Hon. Conrad Dillon, Sir Sydney Waterlow, the Rev. J. Guinness Rogers, and Mr. H. C. Burdett. The Chairman, in opening the proceedings, said that from returns which he had received he found that in Birmingham, where the Hospital Sunday movement was initiated, seventy contributing congregations raised a sum of £5000 for their hospitals. In London and the suburbs there were no less than 2000 contributing congregations, and if they gave to the same extent as those in Birmingham they would raise a sum of £150,000, instead of the £40,000 which they did actually contribute. The deficiencies of the London hospitals were stated at £100,000, but this estimate did not take note of the fact that there were also 2000 beds available, but unoccupied for want of adequate means. If the hospitals were to work at their utmost efficiency a sum of 200,000 would be required. Sir Sydney Waterlow then moved a resolution pledging the meeting to use every endeavour to arouse public interest in the needs of the hospitals, and urging the clergy to make an appeal to their congregations so as to secure that the total sum collected should not be less than £100,000. The Hon. Conrad Dillon seconded the resolution, which was carried unanimously. The Rev. G. T. Palmer then moved a resolution expressing regret at the fact that the expenditure and liabilities of the hospitals in the Newington district exceeded their income by £2800 in the year 1886, and pledging the meeting to increased exertion to prevent any like deficiency during the current year. The Rev. C. H. Spurgeon, in seconding the resolution, said that the hospitals would have inevitably growing needs. But while their liabilities were increasing their incomes were decreasing. People must therefore rouse themselves to make up the deficiencies which had already appeared, and which would continue to appear in greater proportions in the future. From the constant growth of the population of the metropolis more hospitals would be required, and if the tending of the sick and needy could not be properly undertaken by voluntary institutions, the indispensable work would have to be done by Government. He hoped that outsiders would be awakened to the urgency of the case; for it was not only as Christians, but as men, that they contributed to the fund. In giving to the hospitals there need never be any fear of doing injury, for to relieve sickness and suffering must be good. The Rev. J. Guinness Rogers supported the resolution, declaring that the collections hitherto made on Hospital Sunday were not worthy of London's wealth, her humanity, or her Christianity. The resolution having been unanimously carried, the proceedings terminated with a vote of thanks to the Chairman.

On the 14th inst. a meeting was held at the Mansion House. The Lord Mayor, who presided, was supported by Sir S. H. Waterlow, Bart., Alderman Sir W. McArthur, K.C.M.G., M.P., the Bishop of London, the Rev. Dr. Allon, Sir Edmund Hay Currie, Canon Fleming, Dean Vaughan of the Temple, Rev. — Simpson, Mr. Wakley, Mr. H. N. Custance (secretary), Mr. Burdett, and others. The Lord Mayor mentioned the receipt of letters from the Bishop of Bedford, the Bishop of Ripon, Lord Strafford, and the Rev. Dr. Wace, and announced that he had received from Mr. Henry Irving a contribution of fifty guineas. In opening the proceedings, the Chairman said that the promoters of the Hospital Sunday Fund endeavoured to excite in the public, and particularly in the wealthy, feelings of gratitude and thankfulness for the health and prosperity they enjoyed, and as a result to make a special endeavour to support the institutions which were established chiefly for the benefit of those not so fortunate and not so well off as themselves. This year, and this time of the year, when so many of them were spending large sums of money to gratify their feelings of loyalty, curiosity, or enthusiasm, in connexion with Her Majesty's conspicuous jubilee, was particularly suited to be signalised by special liberality in this respect. The Bishop of London then moved a resolution identical with that proposed at the meeting on the 11th inst. by the Marquis of Lorne. It was not anything new, he said, to plead for hospitals in the city where such institutions had been liberally supported from the earliest times. There were no institutions which appealed more strongly to Christian hearts than those which were designed to carry on the work in which their Master had so often engaged, that of relieving and mitigating the sufferings of the sick and afflicted. It was a blessed thing indeed to be permitted to be able to carry on such a work, and it was in truth the very best mode of preaching the Gospel. The Rev. H. Allon, D.D. (Islington), seconded the resolution, and pointed out that the claims of the Fund had been already demonstrated far beyond the need of argument. Experience had proved the need and the value of hospitals and dispensaries, and their care must now be one of practical effort to apply principles that were universally admitted. Referring to the discussion as to the desirability of a Parliamentary grant, the speaker said that money was not the most important thing—sympathy was a necessity, and the need of it had often rendered their Poor-law boards the reverse of what they should be, and had earned for the Charity Organisation Society the unpopularity for which it was notorious. Mr. J. B. Martin, treasurer of Charing-cross Hospital, at this stage attempted to deliver himself of a long and rambling statement as to the refusal of four hospitals to assist the Fund, but was ruled out of order by the Chairman. The motion having been carried unanimously, Sir S. H. Waterlow moved the second resolution, which was similar to the one proposed by him on the 11th inst. Like the first one, it was carried without dissent, and a vote of thanks to the Lord Mayor having been passed, the meeting broke up.

On the 15th inst. a meeting was held in St. Andrew's Hall, Newman-street, W. The St. Marylebone and West Central District, on behalf of which the gathering was held, comprises Marylebone, St. John's Wood, Bloomsbury, Holborn, &c., and contains twenty hospitals and seven dispensaries benefiting from the Hospital Sunday Fund. In the year 1886 these institutions relieved 8980 in-patients and 158,955 out-patients; their income for the same year was £74,274 and their expenditure £84,451. The chair was taken by Major A. H. Ross, M.P., who was supported by Colonel Duncan, M.P., Mr. A. A. Baumann, M.P., and Mr. H. L. W. Lawson, M.P. The Chairman opened the proceedings with a brief speech, in the course of which he pointed out that, taking fourteen of the principal hospitals in London, it was found that their annual average receipts from subscriptions and the Hospital Saturday and Sunday Funds for the past three years amounted to £105,000, while their average expenditure in the same time was £220,000, Colonel Duncan, M.P., then moved a resolution pledging the meeting to use every endeavour to arouse public interest in the needs of the hospitals, and urging the clergy to point out the advantage of giving through the Hospital Sunday Fund, owing to the nominal cost of collection, and to make an earnest appeal to the congregations in order to secure that the whole sum collected should not be less than £100,000. Mr. A. Baumann, M.P., in seconding the resolution, said that nothing less than the £100,000 mentioned in the resolution would suffice if the hospitals were to be relieved from their present financial crisis. The question now was whether the London public preferred to support the hospitals by their voluntary contributions or to submit to having another 2*d.* or 3*d.* added to their rates. In his opinion, it would be a deep reproach to Londoners if they allowed their poorer fellow-citizens to be thrown upon the cold and unsympathetic relief provided by the State in the time of sickness and pain. This resolution having been carried unanimously, Mr. H. L. W. Lawson proposed another expressing regret at the disparity during 1886 between the incomes of the metropolitan medical charities and their expenditure, and pledging the meeting to increased exertion to prevent a like deficiency in the present year. Mr. Arthur Marshall seconded the resolution, which was carried without dissent; and a vote of thanks to the Chairman brought the proceedings to a close.

On the 16th inst. a meeting was held at the Kensington Town Hall. The Duke of Argyle presided, and was supported by, amongst others, Sir A. Borthwick, M.P., Rev. the Hon. E. Carr Glyn, Mr. Brudenell Carter, Rev. Mr. Graves, and Mr. Burdett. The Chairman, in opening the proceedings, expressed the pleasure he had in presiding over a meeting which had for its object the increase of the Hospital Sunday collection. He observed that in no other country and in no other age had there been such a vast aggregation of people as at present residing in London; throughout Christendom there was no other city nearly approaching the population of the metropolis. Provision for sickness

Digitized by Google

and disease, while absolutely necessary, was one of the most difficult problems of modern times. Such provision cannot be left to individuals, it must be met by organisation, voluntary, municipal, or State. That it had hitherto been imperfectly performed was proved by the fact that the hospitals of London and the country were living from hand to mouth, and that many of them had had to close some of their wards. The deficit last year in the funds of the medical charities comprised in the Kensington district amounted to about £18,000, and the question was, how was this deficit to be met? He deprecated State assistance, which would, if resorted to, assuredly put an end to voluntary contributions. In Glasgow organised appeals to the industrial classes had proved highly successful, and he advocated systematic and organised appeals to the working classes of London, believing that if this plan were adopted the deficit in the funds of the metropolitan hospitals would cease to exist. The first resolution, which was in exactly the same terms as the corresponding one at the previous meetings, was moved by Mr. Brudenell Carter, who dwelt on the universality of the claim of hospitals for support. He also opposed State aid, such institutions requiring in their management not red-tapeism but flexibility. Sir A. Borthwick, M.P., seconded the resolution, and announced his intention of endeavouring to organise such an appeal to the working classes as had been suggested by the Duke of Argyle. The motion having been carried unanimously, Mr. Burdett moved the second resolution, which was also identical with the one passed at previous gatherings. He earnestly advised those present to visit the hospitals to see the working of them, and to become personally acquainted with the good they do. The Rev. Carr Glyn seconded the resolution, and advocated not only appeals to the working classes, but also house-to-house collections among the middle classes and the well-to-do. A vote of thanks to the Chairman was then carried with acclamation, and the proceedings terminated.

SANITARY LEGISLATION CONFERENCE.

THIS Conference held its fifth meeting on Tuesday last at Argyll-place, Regent-street, when Mr. C. C. Lacaita, M.P., Dr. Farquharson, M.P., and Dr. Cameron, M.P., who, with Sir W. Guyer Hunter, M.P., and Sir Henry Roscoe, M.P., have charge of the Sanitary Registration of Buildings Bill in the House of Commons, were present. In the absence of the President of the Conference, Sir Joseph Fayrer, Mr. H. Rutherfurd, B.L., occupied the chair, and explained that the object of the present meeting was to confer with members of Parliament on the subject of the second reading of the Sanitary Registration of Buildings Bill. Mr. Lacaita, M.P., said the present Bill was to some extent a compromise with an uneducated public opinion. The clauses of the Bill had been framed more or less on the principle that registration should be compulsorily enforced in those cases where the actual residents had not got it in their power to ascertain the sanitary state of houses in which they lived. There was one very grave omission from the Bill in that respect: the great class of tenement buildings often exhibited conditions inimical to health, but the promoters of the Bill and the Conference had considered this class to be dealt with in this Bill. Supposing the Bill became law more or less in its present shape, there would be little difficulty in extending its provisions in modifying circumstances to tenement buildings. The principle of the Bill obviously was that inspection should not be conducted by public officers as such, but that it should be in the power of every owner, lessee, or occupier to go to any licensed practitioner in sanitary science just as he would go to consult any doctor he chose about his own health; but, on the other hand, that the public authorities should be responsible for the registration of the certificates when given, and for the competency of persons who were to certify, they had the guarantee of the Local Government Board or the other responsible bodies mentioned in the Bill. The Bill was down for the second reading on June 22nd.

General Sir Peter Lumsden proposed that a petition from the Conference be presented in support of the second reading of the Bill. Dr. Farquharson seconded the resolution, which was passed unanimously; and it was resolved to leave the convening of the next meeting of the Conference in the hands of the president, vice-presidents, and hon. secretary.

THE SIXTH INTERNATIONAL CONGRESS OF HYGIENE.

THE sixth gathering of sanitary reformers, representing almost every civilised nation in the world, promises to be an exceptionally brilliant affair. It should have taken place last year, for these congresses are held every two years, and it will be three years next autumn since the Congress last met at the Hague. The exact cause of the postponement is not given, but doubtless the cholera epidemics are not foreign to this delay. In any case, everything has been done to make up for loss of time, and the organisers have certainly succeeded in drawing up a most attractive programme. His Majesty the Emperor of Austria and Hungary has granted a subvention to the Congress, and the Crown Prince, Archduke Rodolphe, is its patron. The highest functionaries of the empire, the leading ministers, notably the President of the Council and Minister of the Interior, Count Taaffe, are honorary presidents of the Congress. All the ministries have appointed special delegates, as also the Diets of Upper and Lower Austria, of Carinthia, Bohemia, Moravia, Silesia, and Galicia. Subventions have also been granted, so that the whole empire will be thoroughly represented. The various leading towns and municipalities have likewise joined the movement, and the Austrian railway companies, together with the Danubian navigation companies, have granted a reduction of 50 per cent. on all fares charged to members of the Congress.

A preliminary meeting of the members of the Congress will be held in the evening of Sept. 25th, and a solemn opening ceremony will take place on the morning of the 26th. In the afternoon there will be an excursion to Kahlenberg. The Congress will sit throughout the week, with the exception of Thursday, when an excursion will be made to Höllenthal, Semmering, and the water intake of Kaiserbrunnen. Numerous receptions are to be held, a club will be provided for the use of the members of the Congress, all institutions of interest at Vienna are to be visited, and facilities given for attending at the theatres. On Monday, Oct. 3rd, a special boat will take the members of the Congress who choose to remain after the debates are terminated down the Danube to Buda-Pesth, where an official reception is announced. After visiting the principal objects of interest in the capital of Hungary, the excursionists are to return on the following day to Vienna. It is probable that from twenty-five to thirty nationalities will be represented, and we are pleased to note amongst those already announced to read papers the names of Professor W. H. Corfield, Mr. Shirley F. Murphy, and Dr. Franklin, from England; together with Dr. Brouardel, Dr. Proust, Dr. Jacques Bertillon, and many other eminent Frenchmen; Dr. Corradi and Dr. Pini, from Italy; Professor Max von Pettenkofer, from Germany; Professor Gruber, from Vienna; Professor Hauser, from Madrid; Dr. Bambas, from Athens; and Dr. A. Beaujon, from Holland. Several doctors from Switzerland, Sweden, Belgium, and Denmark have also promised papers. The subjects selected are of a thoroughly practical character, and the Congress promises to be fruitful in good results. Could not the seventh International Congress of Hygiene be held in London?

NORTH LONDON HOSPITAL FOR CONSUMPTION.—The annual festival in connexion with this institution was held on the 15th inst. at the Langham Hotel, Mr. F. D. Mocatta presiding. Since the foundation of the hospital in 1860, 170,000 patients have been treated. Last year 318 in-patients were received at the hospital at Hampstead, while 2700 out-patients attended at the branch in Tottenham-court-road. In the course of the evening subscriptions to the amount of about £2500 were announced, including a conditional donation of £1000.

THE foundation-stone of a new College of Science, affiliated with Durham University, was laid on the 15th inst. at Newcastle-on-Tyne by Sir W. G. Armstrong. The site covers two acres of ground, and the college will cost, when completed, £20,000.

MEMORIAL PORTRAIT OF

SIR WILLIAM JENNER, BART., K.C.B., M.D.

THE following is a list of the Committees up to June 14th:—

General Committee.

Sir George Burrows, Bart., M.D., Chairman.
Sir James Paget, Bart., Vice-Chairman.
Dr. Charles J. Hare, G. D. Pollock, Esq., } Hon. Treasurers.
Dr. J. Russell Reynolds, Sir Henry Pitman, } Hon. Secretaries.

Adams, Wm., Esq., Regent's-park-road.
Aikin, C. A., Esq., Clifton-place.
Andrew, Dr. James, Harley-street.
Bastian, Dr., Queen Anne-street.
Beck, Marcus, Esq., Wimpole-st.
Best, Palemon, Esq., J.P., Louth.
Birkett, Dr., Russell-square.
Bond, Dr.
Brodie, Dr. G. B., Chesterfield-st.
Brunton, Dr. T. L., Welbeck-street.
Buchanan, Dr. G., Nottingham-place.
Champneys, D., Great Cumberland-place.
Clark, Sir Andrew, Bart., M.D., Cavendish-square.
Corfield, Dr. W. H., Savile-row.
Coupland, Dr., Weymouth-street.
Crawford, Sir T., K.C.B., Director-General, Army Medical Department.
Cribb, Dr. A. J., Highbury.
Duckworth, Sir Dyce, M.D., Grafton-street.
Dukes, Dr. Clement, Rugby.
Duncan, Dr. J. Matthews, Brook-street.
Erichsen, John, Esq., Cavendish-place.
Fairbank, Wm., Esq., Windsor.
Fayrer, Sir Joseph, K.C.S.I., M.D., Wimpole-street.
Fearnside, Henry, Esq., Kensington.
Frank, Dr.
Garrod, Dr. A. B., Harley-street.
Gee, Dr., Wimpole-street.
Gowers, Dr., Queen Anne-street.
Greenfield, Dr. W. S., Edinburgh.
Greenhow, Dr., Reigate.
Gull, Sir Wm., Bart., M.D., Brook-street.
Harley, Dr. G., Harley-street.
Hewitt, Dr. Graily, Berkeley-sq.
Hickman, Wm., Esq., Dorset-sq.
Hill, Berkeley, Esq., Wimpole-st.
Holderness, W. B., Esq., Windsor.
Hughes, H. Spencer, Esq., Bromley.
Ingham, Dr. Amos, Haworth.
Jackson, Dr. J. H., Manchester-sq.
Jackson, T. V., Esq., Mayor of Wolverhampton.
Jessett, Fredk. B., Esq., Upper Wimpole-street.
Jones, Dr. T. Ridge, Chesham-pl.
Jones, Dr. J. Talfourd, Eastbourne.
Knapton, Geo., Esq., Southport.
Legg, Dr. J. Wickham, Green-st.
Lister, Sir Joseph, Bart., Park-crescent.
Marsh, Howard, Esq., Bruton-st.
Marshall, John, Esq., J.P., Dover.
Marston, Dr. J. A., Army Medical Department.
Martin, Dr. R., Queen Anne-st.
Martin, A. H., Esq., Evesham.
Merriman, John, Esq., Kensington.
Money, Dr. Angel, Harley-street.
Monro, Dr. Henry, Upper Wimpole-street.
Moore, Dr. W. W., Brighton.
Oliver, Dr. George, Harrogate.
Patten, C. A., Esq., Ealing.
Pavy, Dr., Grosvenor-street.
Philipson, Dr., Newcastle-on-Tyne.
Playfair, Dr., George-street, W.
Poore, Dr. G. V., Wimpole-street.
Potts, Wm., Esq., Albert-terrace.
Powell, Dr. R. D., Wimpole-street.
Quain, Dr. Richard, Harley-street.
Rigden, Walter, Esq., South Kensington.
Ringer, Dr. Sydney, Cavendish-place.
Roberts, Dr. F. T., Harley-street.
Royle, Arnold, Esq., Army Medical Staff.
Saunders, Sir Edwin, George-st.
Scott, Dr. H., Upper Woburn-pl.
Semple, Dr. R. H., Torrington-sq.
Sewell, Dr. C. B., Cavendish-sq.
Snow, Dr. H. L., Bayswater.
Squire, Dr. Wm., Orchard-street.
Stone, Dr., Sanctuary.
Thompson, Sir Henry, Wimpole-street.
Thompson, Dr. E. S., Cavendish-square.
Thompson, Joseph, Esq., Nottingham.
Waggett, Dr. John, Bournemouth.
Wallace, Dr., Southsea.
Whiting, Dr. H. Townsend.
Williams, Dr. John, Queen Anne-street.
Wood, Dr. Wm., Harley-street.

Executive Committee.

Sir Henry Thompson, Chairman, 35, Wimpole-street, W.
Adams, William, Esq., Tower Lodge, 2, Regent's-park-road, N.W.
Dr. George Vivian Poore, 30, Wimpole-street, W.
Dr. Chas. J. Hare, Berkeley House, Manchester-square, W.,
George David Pollock, Esq., 36, Grosvenor-street, W. } Hon. Treasurers.
Dr. J. Russell Reynolds, 38, Grosvenor-street, W.,
Sir Henry Pitman, 28, Gordon-square, W.C. } Hon. Secs.

Anyone desiring to have his name added to the General Committee should signify the same without delay to either of the Honorary Secretaries.

Subscriptions may be sent to any one of the Hon. Treasurers or Hon. Secretaries.

June 14th, 1887.

MEDICAL TRIAL.

RESTORATION OF A DENTIST'S NAME TO THE REGISTER.

REG. *v.* THE GENERAL MEDICAL COUNCIL.

JUDGMENT was delivered on Wednesday last by Mr. Justice Mathew in this case, which was an application on behalf of Mr. H. F. Partridge for a *mandamus* ordering the General Council of Medical Education of the United Kingdom to restore the name of Mr. Partridge to the Register of Dentists kept under the Dentists Act, 1878. The rule was argued last sittings before Mr. Justice Mathew and Mr. Justice A. L. Smith.

Mr. Justice Mathew now delivered the judgment of the Court. His Lordship said the applicant had, since 1867, practised in the metropolis as a dentist, and it was admitted that when the Act passed he would have been entitled to be registered as a dentist if an application had been made by him in accordance with the provisions of Section 7. He had not, however, applied for registration in respect of this qualification. In 1878 he obtained from the Royal College of Surgeons, Ireland, a diploma in dentistry, and as a licentiate of this body, which was one of the medical authorities referred to in the Act, he applied for and procured registration under the statute (Section 6). The diploma had been granted on the terms that the holder should not seek to attract business by advertising or by any practice considered by the College unbecoming, and that the diploma might be cancelled on its being proved to the satisfaction of the President and Council that he had done so. In the year, 1883, the Royal College of Surgeons of Ireland, upon the ground that Mr. Partridge had advertised for business, cancelled his diploma, and thereupon the General Council directed his name to be erased from the Register. Section 11 contains provisions as to the corrections to be made from time to time in the Register, and it was argued for the General Council that, where the original qualification no longer existed, the Council were bound to correct the Register and erase the name. It was argued for the applicant that the name of a person qualified either by practice or diploma and once properly placed on the Register could only be erased in the manner and upon the grounds specified in the statute It was urged that the mere fact that the diploma had been cancelled by the medical authority which had granted it, was not a ground upon which the General Council was justified in disqualifying the applicant or exposing him to the penalties imposed by the Act upon unqualified practitioners. We are of opinion that the contention of the applicant is right and that he is entitled to have his name restored. [His Lordship here read Section 13, and also referred to Section 15.] It appears to us that, in such a case as the present, the Medical Council possessed no further powers of dealing with the Register than those conferred in the sections referred to. It was admitted that the Council had not decided that Mr. Partridge had done anything to justify the removal of his name under Section 13, but had considered that they were bound to erase his name when the determination of the medical authority granting the diploma had come to their knowledge. This is a course which, it seems to us, they were not entitled to adopt, otherwise where a medical authority has withdrawn a diploma on the ground, for instance, that a particular theory of dental surgery had been adopted or discarded, the name of the holder must be struck from the register. But this is a ground upon which the General Council under Section 13 are expressly prohibited from erasing a name. The third clause of Section 13 appears to show that the Council was not intended to be bound by any determination of the medical authority, even with respect to the grounds for erasing a name specified in Section 13, but was required to adjudicate independently. This view is strengthened by an examination of the provisions in the last clauses of Sections 13 and 14. The Act appears to be carefully framed to restrict the right of the General Council to interfere with registered dental practitioners in the practice of their profession to the cases where there are the grave reasons for disqualification specified in Section 13.

The rule for a *mandamus* was accordingly made absolute, but, on an application on behalf of the Council, was ordered not to be drawn up for a week.

Mr. Finlay, Q.C., and Mr. Lyon were for the applicant; and Mr. Kennedy, Q.C., and Mr. Muir Mackenzie for the Council.

THE Lord Chancellor has received a memorial from the laity of the Church of England praying for a limitation to be imposed by authority on the publication of obscene and unnecessary details of divorce and criminal cases. The memorial was signed by 124 peers, 46 medical men, 76 officers of the army and navy, and 44 solicitors, there being altogether 4000 signatures.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 6237 births and 3340 deaths were registered during the week ending June 11th. The annual rate of mortality in these towns, which had been 20·4 and 19·5 per 1000 in the preceding two weeks, further declined last week to 18·9, and was lower than in any preceding week of this year. During the first ten weeks of the current quarter the death-rate in these towns averaged 20·3 per 1000, and was 1·5 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 11·3 in Leicester, 13·2 in Portsmouth, 13·3 in Bristol, and 13·9 in Derby. The rates in the other towns ranged upwards to 24·6 in Newcastle-on-Tyne, 27·6 in Oldham, 28·9 in Manchester, and 29·4 in Birkenhead. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 532, 522, and 521 in the preceding three weeks, further declined last week to 489; they included 227 from measles, 127 from whooping-cough, 55 from scarlet fever, 31 from "fever" (principally enteric), 29 from diarrhœa, 17 from diphtheria, and only 3 from small-pox. No death from any of these zymotic diseases was registered during the week in Leicester or in Derby; while they caused the greatest mortality in Manchester, Salford, Oldham, and Norwich. The highest death-rates from measles occurred in Brighton, Birkenhead, Sheffield, Newcastle-upon-Tyne, Salford, Oldham, Manchester, and Norwich; from whooping-cough in Liverpool and Norwich; from scarlet fever in Birkenhead; and from diarrhœa in Preston. The 17 deaths from diphtheria in the twenty-eight towns included 9 in London, 3 in Oldham, and 2 in Bradford. Small-pox caused 2 deaths in Sheffield and 1 in Birmingham, but not one either in Greater London or in any of the twenty-five other large provincial towns. Only one case of small-pox was under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease; and no new case was admitted to these hospitals during the week. The deaths referred to diseases of the respiratory organs in London, which had been 333 and 264 in the preceding two weeks, further declined last week to 259, and were two below the corrected weekly average. The causes of 70, or 2·1 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leicester, Nottingham, Portsmouth, and in six other smaller towns. The largest proportions of uncertified deaths were registered in Oldham and Sunderland.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 22·6 and 19·8 per 1000 in the preceding two weeks, rose again to 21·9 in the week ending June 11th; this rate exceeded by 3·0 the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 18·7 and 19·2 in Leith and Greenock, to 22·7 in Perth and 27·3 in Paisley. The 546 deaths in the eight towns last week showed an increase of 51 upon the number in the previous week, and included 35 which were referred to whooping-cough, 12 to diarrhœa, 9 to scarlet fever, 8 to "fever" (typhus, enteric, or simple), 8 to measles, 4 to diphtheria, and not one to small-pox; in all, 76 deaths resulted from these principal zymotic diseases, against 82 and 50 in the preceding two weeks. These 76 deaths were equal to an annual rate of 3·0 per 1000, which was 0·2 above the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 43 and 32 in the preceding two weeks, rose again last week to 35, and included 11 in Glasgow, 9 in Edinburgh, 6 in Dundee, 4 in Greenock, and 4 in Leith. The deaths from each of the other zymotic diseases also showed an increase upon the low numbers in the previous week. The deaths attributed to diarrhœa exceeded by 5 the number returned in the corresponding week of last year. Of the 9 fatal cases of scarlet fever, 6 occurred in Glasgow and 2 in Dundee; while 6 of the 8 fatal cases of measles also occurred in Glasgow. Five of the 8 deaths referred to "fever," and 3 of the 4 fatal cases of diphtheria, were also returned in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 126, 109, and 102 in the preceding three weeks, rose again last week to 109, and exceeded the number returned in the corresponding week of last year by 19. The causes of 72, or more than 13 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 24·1 and 21·4 per 1000 in the preceding two weeks, rose to 31·2 in the week ending June 11th, considerably exceeding the rate in any recent week. During the first ten weeks of the current quarter the death-rate in the city averaged 29·0 per 1000, the mean rate during the same period being but 18·4 in London and 19·8 in Edinburgh. The 211 deaths in Dublin last week showed an increase of no less than 66 upon the number returned in the previous week; they included 18 which were referred to measles, 3 to "fever" (typhus, enteric, or simple), 3 to scarlet fever, 2 to whooping-cough, 2 to diarrhœa, 1 to diphtheria, and not one to small-pox. Thus the deaths resulting from these principal zymotic diseases, which had been 27 and 21 in the preceding two weeks, rose last week to 29, and exceeded the number returned in any previous week of this year; they were equal to an annual rate of 4·3 per 1000, the rates from the same diseases being 3·0 in London and 2·8 in Edinburgh. The fatal cases of measles, which had been 8, 17, and 10 in the preceding three weeks, rose last week to 18, and exceeded the number in any previous week of this year. The deaths from the other zymotic diseases scarcely differed from those returned in the previous week, the 3 deaths from "fever" corresponding with the number in each of the preceding two weeks. Compared with the numbers in the previous week the deaths of infants showed a decline, while those of elderly persons had considerably increased. Three inquest cases and 4 deaths from violence were registered; and 55, or more than a fourth, of the deaths occurred in public institutions. The causes of 25, or very nearly 12 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

Brigade Surgeon Ramsden and the Officers of the Army Medical Staff at Alexandria entertained Surgeon-General O'Nial, C.B., at dinner at the Mohamed Ali Club, prior to his departure for England by the Messageries Maritimes mail steamer.

Surgeon-Major F. W. Trevor has assumed the medical charge of the military prison, and of the officers, women, and children in the North Camp, Aldershot, relieving Surgeon-Major J. W. Morgan, whose time of appointment has expired.

Brigade Surgeon J. Paxton, Colchester, has been appointed officiating Principal Medical Officer, Eastern District, during the absence on leave of Deputy Surgeon-General T. W. Fox.

INDIA OFFICE.—The Queen has approved of the following promotions among the Officers of the Staff Corps and Indian Military Forces, made by the Governments in India:—Surgeons to be Surgeons-Major (dated March 31st, 1887): George Spiers Alexander Ranking, M.D., Robert Davidson Murray, Dennis Wood Deane Comins, Patrick Fenelon O'Connor, James Moran, M.D., William Beatson, William Allason Simmonds, Roderick Macrae, Thos. Elwood Lindesay Bate, and Shibram Borah, of the Bengal Medical Establishment; Surgeon G. Tucker Thomas (dated March 31st, 1887), Surgeon Arthur James Sturmer (dated March 31st, 1887), and Surgeon Archibald Adams, M.D. (dated March 31st, 1887), of the Madras Medical Establishment; and Surgeon Arthur Henry Coles Dane, M.D. (dated March 31st, 1887), Surgeon John Philip Greany M.D. (dated March 31st, 1887), Surgeon John Edward Ferguson (dated March 31st, 1887), Surgeon George Edward Elton Burroughs (dated March 31st, 1887), and Surgeon James McCloghry (dated March 31st, 1887), of the Bombay Medical Establishment.

ADMIRALTY.—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Fleet Surgeon Walter F. Cope Bartlett has been placed on the retired list.

Digitized by Google

with permission to assume the rank of Deputy Inspector-General of Hospitals and Fleets (dated June 9th, 1887).

The following appointments have been made:—Fleet Surgeon James Flanagan, to the *Castor;* Fleet Surgeon Edwd. Meade, to the *Cambridge;* and Fleet Surgeon George Mair, to the *Iron Duke.*

Correspondence.

"Audi alteram partem."

"PASTEUR'S METHODS."

To the Editors of THE LANCET.

SIRS,—Will you kindly permit me to offer some remarks in reply to "R.J.P.S.," who writes on the above subject in your issue of the 23rd of April. Your correspondent says that while expressing my anxiety that the dangers of M. Pasteur's prophylactic treatment for hydrophobia should be recognised, I seem somewhat to ignore the much greater danger of untreated bites from rabid animals. But as in my humble opinion, M. Pasteur's methods when they are not hurtful are inefficacious, I submit "R. J. P. S." begs the question. If M. Pasteur's intensive method is attended with the risks indicated by M. Peter clinically, and by von Frisch and others experimentally, it surely introduces an additional danger, since in no case can we be certain that the victim of a bite has been inoculated with rabic virus, though according to M. Pasteur all cases must be dealt with on the assumption that infection has occurred. Here, then, in addition to the danger which is involved in the bite, we have that which may follow the intensive treatment. Your correspondent admits that some of the deaths which have occurred during the present year "very possibly" resulted from the treatment: that being so, I think the concession ought to follow that the experimental test—which M. Pasteur admits to be crucial, and by which he obtained results which neither von Frisch, nor Renzi, nor Amoroso could obtain—should be as expeditiously as possible carried out openly in the presence of those who are opposed to him, and that in the meantime M. Pasteur should revert to his former method, which is comparatively, if not quite, harmless. Your correspondent holds that "it is largely a question of statistics." No doubt that is so, but not of statistics founded on possibilities which are to be accepted as facts. Now, if he accepts M. Pasteur's figures and the deductions which he and his partisans draw therefrom, he will find that cases of hydrophobia in France and Algeria rose suddenly and unaccountably, and without any corresponding increase of rabid animals, from about 50 to 308, omitting all notice of those deaths which occurred outside M. Pasteur's practice. Thus, taking their estimate of 16 per cent. as the incidence of hydrophobia in rabid animal bite cases, and the number of French and Algerian patients treated by M. Pasteur in 1886 at 1929,[1] we have 308. Trousseau told his pupils that hydrophobia was a disease which very rarely occurred in the human subject, and that in France, with a population of more than 36,000,000, only 20 to 25 cases of the disease occurred annually. More recently the average has been fixed at 30. Now, allowing 20—an excessive estimate—for Algeria, we have 50. Then again, how are we to account for the extraordinary circumstance that, notwithstanding M. Pasteur's method, the average annual mortality from hydrophobia in France has not been reduced, but, on the contrary, according to French authorities, it has increased nearly one-third? I have recently submitted to the Government of Bengal a report, founded on the returns of animal bite treated at the dispensaries in Bengal with the local application of potassic permanganate, as advocated by me in 1881, and here furnish some statistical information which, to my mind, is most significant as illustrating the uncertainties of infection with rabic virus in animal bite. I must premise that as a test of the efficacy of the treatment I regarded the returns as unsatisfactory. A reference to your issue of January 29th, 1887, will show that of the forty-eight persons supposed to have been bitten by rabid wolves, seven died. This gives a percentage of 14·58, not 14·0, as M. Grancher has it. Now, the returns with which I had to deal showed forty-two cases of supposed rabid jackal bite, with six deaths, or 14·28 per cent., 0·30 per cent. in favour of the cases in which M. Pasteur's method found no place, and this, too, after eliminating some cases in which the animals had attempted to carry off infants from hunger, and in which no mortality had occurred. Here the jackal takes the place of the wolf, and so far as is known, with the exception of the circumstances mentioned above, it never attacks except when rabid. The fact is, that statistics dealing with methods in cases of doubtful infection are very unsatisfactory, as the data are often of a most erratic character. Take for instance, the following example: At Chumparun twenty-four persons, consisting of ten men, eight women, and five boys, and one of whom no information is afforded, were attacked in one evening by a rabid jackal. This occurred in the beginning of the year 1886. Twenty-three of these people came under the treatment of the assistant-surgeon, but although potassic permanganate was applied, my instructions were not strictly observed. Four of these people died, but, strangely enough, not a single one of the ten men was affected, the victims being three women and one boy. Then again, I found that, after eliminating clearly unsatisfactory cases in which there was no death, of twenty-seven women who were bitten and treated, seven, or 25·9 per cent., and of twenty-four children, four, or 16·6 per cent., died; while only two of the 123 men, or 1·6 per cent., succumbed; and that out of twenty-four men bitten by rabid jackals, only one, or 4·1 per cent., died. Who, may I ask, is justified after this in relying upon statistics alone as proof of the value of his methods of treating cases of this kind? Surely it is not unreasonable to demand that the following question shall be definitely answered and demonstrated by M. Pasteur: Does his method prevent rabies in the dog after it has been infected in the only natural way that infection takes place—namely, by inoculation with the saliva?

In conclusion, allow me to point out a significant fact, and one that should be noted as evidence of M. Pasteur's ever-changing tactics. A medical man in India imagined himself to have been bitten by a rabid dog which had bitten three others, who, so far as we are informed, still remain unaffected, and submitted himself to M. Pasteur's treatment. In his own words I give the description of treatment adopted in his case: "I had to go and be inoculated morning and evening for six days; then every morning for five days. I was finished last Friday, but they asked me, if not inconvenient, to stay in Paris for five or six days more, and then report myself, when a few more inoculations *might* be necessary. After that they said, 'You can go with the most perfect confidence.' They begin with virus fourteen days old, and go on up to that only five days old; they don't use any stronger than that, but virus under seven days will infallibly give a dog rabies."[2] Assuming this to be an accurate description of his treatment, who, with the words of MM. Pasteur, Grancher, and Vulpian ringing in his ears, is not justified in exclaiming, as to M. Pasteur's "methods"—*Credat Judæus apella!*

I am, Sirs, yours truly,

May 14th, 1887. VINCENT RICHARDS.

[1] M. Grancher's figures, THE LANCET, Jan. 29th, 1887.

"PLACENTA PRÆVIA."

To the Editors of THE LANCET.

SIRS,—Dr. Barnes's criticism on my case of Placenta Prævia in THE LANCET of June 4th, is not quite clear to me. He approves of detaching the placenta, but not of the version and plugging the cervix with the breech. Does he appreciate the conditions of the case? I went to it not knowing its nature, and, not possessing his hydrostatic bags, I had to resort to other methods. Having detached the placenta from the whole of its attachment, ruptured the membranes, and the liquor amnii having escaped, a foot was brought down, which I fondly imagined did efficiently compress the placental zone of the uterus and stop the hæmorrhage; but Dr. Barnes objects to my *propter hoc*, and says this was due to the detachment of placenta only. Would he, if called to a similar case, *without his hydrostatic bags*, have been content to detach the placenta, put on a binder, and leave the case to nature after such sudden and alarming hæmorrhage? The child had virtually no claim to consideration at the seventh month, of a delicate mother, and two generations' heredity of a fell disease; but had it been

[2] Indian Medical Gazette for April, 1887.

Digitized by Google

an expectant heir, I should still have turned, but completed the labour, having used more oxytocic agents, and dealt with post-partum hæmorrhage as it required. I have just refreshed my knowledge of this subject by reading Dr. Barnes's clinical lecture on Placenta Prævia in THE LANCET, vol. i., 1861. The third case there related has many points in common with mine. The woman at 4 A.M. was found faint and anæmic from loss of blood; placenta quite over centre of os, which was the size of half-a-crown; no bleeding and no pains at time of examination; but delivery was urgent from exhaustion; so the placenta was detached from the lower zone of the uterus, a bag applied, and the cervix freely expanded in about five minutes, but no pains. "I was, however, enabled to pass my hand by the placenta and reach the membranes, which I ruptured with a skewer..... head was presenting. A foot was easily seized. I ascertained that neither cord nor heart was pulsating.....Child extracted.....premature and stillborn. Uterus made to contract by pressure.....the placenta was speedily cast and withdrawn. No hæmorrhage followed the labour. The patient recovered well. In this case, *had I not possessed the caoutchouc dilator*, I should have been compelled to stretch open the cervix with my fingers at the risk of injury, or to encounter the alternative risk of renewed flooding and a lingering labour, with exhausted uterine power. If the uterus still remain flaccid, and if hæmorrhage continue, or generally *where the patient is much exhausted*, so that effective muscular contraction cannot be roused, artificial aid is called for in order to accelerate delivery." He then advises version, if the cervix can be easily expanded (as in my case), or, if undilated and rigid, to use the bags. There was no need to dilate either with bags or fingers, and version was accomplished with the greatest facility and with a happy result. Would Dr. Barnes have completed delivery at once, without uterine pains, or would he have waited?

I am, Sirs, yours truly,

Spondon, Derby, June 13th, 1887. B. WALKER.

TERRIER'S NEPHRECTOMY.

To the Editors of THE LANCET.

SIRS,—In your issue of June 4th you give a leading article under the above heading, and in referring to a paper in the *Revue de Chirurgie*, by M. Terrier, speak of the method as a new one. Two years ago I removed a large diseased kidney by an operation which seems to me essentially like the one you describe. After opening the abdomen over the site of the tumour, I incised the visceral peritoneum vertically over the kidney, enucleated the diseased organ, and carefully stitched the edges of the visceral peritoneum to the margin of the wound, thus completely shutting out the peritoneal cavity from the field of operation, and especially from the cut ureter, the wound being drained to the front. This operation I have since seen performed by one of my colleagues. At the time I did not think there was anything new in the operation, supposing that what seemed to be such an obvious method of shutting out the peritoneal cavity and draining the wound must have been followed out by others. It is my intention in my next nephrectomy to perform the operation in an exactly similar manner; but, instead of draining forward, to push a trocar through the loin, and through the opening so made to pass the detached ureter, together with a celluloid or some firm drainage tube, and afterwards to completely close the anterior incision. As the question has now come to the front, I will take an early opportunity of giving a detailed report of the case.

I am, Sirs, yours truly,

Leeds, June 6th, 1887. A. W. MAYO ROBSON.

TRANSFUSION.

To the Editors of THE LANCET.

SIRS,—In your issue of June 4th, Dr. J. Graham Brown has pointed out that, in a paper on a case of Transfusion which appeared in THE LANCET of April 16th I erroneously attribute the method there described to Mr. Annandale, whereas it was really introduced by Mr. J. M. Cotterill. I beg to be allowed to thank Dr. Graham Brown for making the correction, and to at once acknowledge and express my regret for the error into which I was led by the fact that the leaflet of instructions furnished by the instrument maker with the apparatus described the method as "Mr. Annandale's." In reply to a letter of inquiry from me, Mr. Cotterill has most courteously furnished me with a succinct statement of the facts of the matter, which I shall esteem it a favour if you will allow me to quote:—

"1. The fact that phosphate of soda solution prevents coagulation of the blood has been known for many years. 2. Dr. Braxton Hicks is reported (Bryant's Surgery) to have suggested its use in transfusion, but whether he actually used it or not I do not know. 3. I performed the operation, as described in the leaflet, in 1883, and taught it to my class of practical surgery as the best method. 4. Two years subsequently Dr. John Duncan, of Edingburgh, performed the operation upon my very strong recommendation, and by the same method. He repeated it frequently, and made some further suggestions, which he published in the *British Medical Journal* of Jan. 30th, 1886. 5. Mr. Lawson Tait read a paper before the Midland Society on the subject, in which he connected Mr. Annandale's name with the operation. No contradiction of this was made, and it is probable that he was led into the mistake in the same way as yourself. 6. Mr. Annandale has authorised me to state that he has had no connection with the introduction of the method, though he has performed it upon several occasions."

I am, Sirs, your obedient servant,

Savile-row, June 10th, 1887. WARRINGTON HAWARD.

THE BATH WATERS AND ARSENIOUS ACID.

To the Editors of THE LANCET.

SIRS,—In a letter on the above subject, which appeared in your issue of January 8th this year, I gave expression to the belief that in the certain discovery of arsenious acid in the Bath thermal waters an explanation was obtained of their behaviour under certain conditions which hitherto had been inadequately accounted for. Since then further very careful experiments have been made for me by my friend, Mr. Gatehouse, with the result that we are in a position to state that a gallon of the waters in question contains as nearly as possible $\frac{1}{10}$ gr. of AS_2O_3. Can this amount be held responsible in any way for the "marvellous efficacy" of these waters in the diseases for which they are extolled? We find that even in the case of resident patients, in whose cure change of air can have had no share, chlorosis succumbs very readily to the waters, taken internally. May not the arsenious acid be the cause here? The amount of iron present per gallon is only $\frac{1}{2}$ gr.—therefore the ratio of the amount of water that contains an ordinary dose of iron to the amount that contains an ordinary dose of arsenic is that of five to four. From this it will be seen that, small as the amount of arsenious acid present may be, the share it takes in the action of the waters is probably great. The amount of arsenic eliminated from the salts of bismuth in the purifying process is small, but there is a great difference between the actions of the purified and unpurified salts. From this it appears that the action of arsenic when in a natural compound is much more marked than its action when given in a prepared form. I am strongly disposed to think that certain reagents—among which I would class arsenic—are specially efficacious when administered in their so-called natural state, as obtains in natural springs, both cold and hot.—I am, Sirs, yours truly,

Bath, June, 1887. T. PAGAN LOWE, M.R.C.S., L.R.C.P. Ed.

THE CONTAGIUM OF SCARLET FEVER.

To the Editors of THE LANCET.

SIRS,—In your issue of last week you noticed in an annotation the most recent work that has been carried on in respect to the *materies morbi* of scarlatina, and, in stating the general conclusions arrived at in that research, you indicated the attitude of guarded reserve in which they must for the present be regarded. Dr. Edington's paper has in the meantime been printed, and a careful survey of its contents seems to me to fully justify the spirit in which your remarks were made. Attention has already been fully directed to the observations of Dr. Klein, and the conclusion arrived at by him based on results of the most unequivocal nature. His conclusion is directly and diametrically opposed to that now under consideration. The issue thus raised is fortunately a direct and limited question of fact; it is, moreover, satisfactory to find that Dr. Edington's statement is sufficiently explicit to

Digitized by Google

render it readily susceptible of confirmation or disproof. Amongst many organisms found by him in scarlet fever blood and desquamation, the description of which is a distinct addition to our knowledge of the disease, is a small bacillus 0·4 μ in breadth and 1·4 μ in length, which he describes as the specific virus of the disease. This organism is found in the blood of patients up to the third day, and in the desquamation on and after the twenty-first day: in the intermediate period of eighteen days it cannot be demonstrated in any of the tissues examined. Obtained as a pure cultivation in nutrient media it has distinctive specific characteristics in its mode of growth, and if inoculated into calves, guinea-pigs, or rabbits, it produces a disease closely resembling scarlatina, and ending in a desquamative stage. Closely associated with this organism is a micrococcus form, of frequent occurrence in the blood and desquamation, but without pathogenetic effects if inoculated. It is noted, however, that in cases where a vivid and general rash is observed, this organism is a constant concomitant of the so-called "bacillus scarlatinæ"; and, supposing the observations to be as careful and accurate as their mode of presentation to the public would lead us to infer, this point may well call for further investigation, for it must strike everyone at all acquainted with the history of such researches that the life history ascribed to this "bacillus scarlatinæ" is strange and unnatural. A solution in the continuity of its demonstrable presence extending over eighteen days is, to say the least of it, a very suspicious point in its behaviour; and it will necessitate a very strict scrutiny of the conditions associated with its reappearance in the desquamation, to establish its identity in its two manifestations, and to exclude the possibility of aerial contamination under an aseptic dressing three weeks old. Although there are strong points in its technical arrangement which commend this research to favourable consideration, there are some grave omissions in the detailed account before me. The bacillus as found in the blood is not figured, nor are we told whether it is readily demonstrable from its large numbers, or only found in isolated scarcity, in that medium. Neither is any hint given as to the manner of its disappearance from the blood. It does not appear to have been found in the urine, and although spore formation is mentioned, it is neither figured nor described. The suggested *rationale* of its disappearance as due to an exhaustion of its special pabulum is obviously but an *obiter dictum*. There is also a lack of control experiments in regard to organisms normally present in the skin. Until these points are more fully elucidated, it is not possible to accept this bacillus as the *materies morbi* of scarlatina.

In view of the interest at present attaching to the question of the zymotic origin of the disease, it may not be out of place to refer to some of the best known recent publications which have appeared upon the subject. I need not refer to the statement of Dr. Klein's results, already detailed in THE LANCET of May 28th, nor repeat the facts observed by Mr. Power, but refer to some prior investigations of which Dr. Klein's paper affords confirmation, and to which it adds the conclusiveness they themselves lacked. Coze and Feltz ("Maladies Infectieuses," 1872) described a diplococcus in connexion with the disease which they looked on as a causal agent in its production. Pohl-Pincus (*Centralblatt f. d. Med. Wissenschaft*, 1883) described a similar organism in the desquamation, on the skin surfaces, and on those of the palate and pharynx. Crooke (THE LANCET, 1883) described a large bacillus in the last of these situations; but in a subsequent paper from Eberth's laboratory (*Fortschritte der Medicin*, 1885), he recounts the results of a long series of experiments in which micrococci were found, chiefly in the tissues of the neck, and more rarely in distant internal organs. He does not appear to have examined the blood in these cases. In a few very severe cases bacilli made their appearance at the end of the second or the beginning of the third week, but they were not seen in ordinary cases, and he does not ascribe any pathogenetic significance to their presence. Bokai of Buda-Pesth ("Orvosi Hetilap," 1885) found micrococci single and in chains in the post-scarlatinal joint affections. A negative result is recorded by Cornil and Babes ("Les Bactéries," 1885), who examined the desquamation for the presence of organisms. The organisms normally present on the human skin are no less important in their relation to the present question; they are described by Bizzozero (Virchow's *Archiv*, Bd. 98 iii., 1884), and by Bordoni-Uffreduzzi (*Fortschritte der Medicin*, 1886). The latter describes five varieties of micrococci and two of bacilli as normally present. His description of one of the latter, B. epidermis, so closely resembles that given by Edington of his B. scarlatinæ, as to suggest their identity.

I remain, Sirs, yours obediently,

June 15th. M.D.

THE PRACTICAL ELEMENT IN MEDICAL EDUCATION.

To the Editors of THE LANCET.

SIRS,—Requiring an assistant lately to help in my surgery, I engaged a gentleman who said he had been taught practical pharmacy at a large London Hospital. Finding him very slow in dispensing, I made inquiries. He tells me he was never allowed to make up a prescription for a patient, or even to compound a stock mixture. He had never made a pill, and did not know how to spread a blister. He was simply shown the drugs and told to learn their composition and uses, and for this he had to pay four guineas. He then goes to the College of Physicians and passes his examination in materia medica, the chief questions being the action of the alkaloids on the system, and all this before being taught to compound medicine. Sir W. Gull may deprecate drugs, but the large majority of medical men, as well as their patients, believe in their efficacy, and what is wanted is to teach the student the real practice of the medical art, such as he will need in his after professional life. I do hope that the appointment of Dr. Glover's committee will lead to some form of the old apprenticeship being made compulsory. It would be more useful than attending routine lectures, which most students hate and would gladly dispense with.

I am, Sirs, yours truly,

June, 1887. A GENERAL PRACTITIONER.

NORTHERN COUNTIES NOTES.

(*From our own Correspondent.*)

THE NEWCASTLE EXHIBITION.

LAST week must be considered a most successful one for our Exhibition, as nearly 120,000 visitors went up to the Moor. The weather was very dull on Saturday, but towards evening it underwent a favourable change, which has still continued. An accidental circumstance has given a variety to the throng of excursionists in our city. A few days ago the Chinese steamer Toonan came into the Tyne, with nearly 700 "Celestial" sailors on board. They have come to take charge of some Chinese war ships now fitting up at Sir W. Armstrong's. These sailors crowd the streets, and create no little curiosity as they go about in their picturesque groups.

SUNDERLAND.

Mr. A. E. Harris, medical officer of health for Sunderland, is to be congratulated on the present sanitary condition of his borough. During the past week the death-rate was only 15·7, being the lowest point indicated in the list of the twenty-eight great towns. The epidemic of measles, which for some time had assumed so alarming an aspect, appears now to be practically suppressed. A few years ago Mr. Harris, on his appointment to the borough, found a very serious state of matters, and the way he had to grapple with many sanitary abuses before he could effect their removal would have tried the patience of many less determined officers. He is now rewarded, however, for his up-hill work in the present sanitary state of Sunderland.

GATESHEAD.

A letter has been received by the Gateshead Town Council from the Lord Chancellor's secretary, recommending the appointment of new magistrates. Many of your readers will be glad to hear that Dr. George Douglass of Gateshead is included in the list.

HEXHAM.

Lieut.-Colonel Nicholson, who died at his seat, Halliwell Dene, Hexham, on Friday night last, in his sixty-eighth year, was formerly a member of our profession, having served his time to the late Dr. Jefferson of Hexham, and on becoming qualified practised for a few years with much success in this ancient abbey town, but about

Digitized by Google

twenty years ago he was enabled by fortunate circumstances to exchange the life of a practitioner for that of a country gentleman. He joined the Volunteer movement at its commencement, and rose through its offices until, on the death of the late Earl of Durham, he was further promoted to the command of a battalion, from which position he retired about seven years ago, and was allowed to retain the honorary rank of lieutenant-colonel. He was active in all that pertained to the welfare of Hexham and its district, and retained to the last a warm feeling for his old profession. The writer was present a couple of years since at a meeting presided over by Dr. T. Stainthorpe of Hexham, when this gentleman (whom I am glad to say is still hale and hearty) attained his jubilee in practice at Hexham, and the manner in which he alluded to his old companion in practice, and to his old profession, did equal honour to his heart and mind. In politics the deceased gentleman was a Conservative; he was widely known and respected by all classes. He leaves a widow and daughter, and two sons, the eldest of whom is practising as a solicitor in Hexham.

Newcastle-on-Tyne, June 7th.

EDINBURGH.

(From our own Correspondent.)

ST. ANDREW AMBULANCE ASSOCIATION.

A DEMONSTRATION of ambulance work was given by members of the Scottish Ambulance Association, in the Waverley Market Hall last week, under the presidency of Sir Thomas Clark, Lord Provost of Edinburgh. The hall is a capital place for such purposes, being capable of containing 30,000 people. On the present occasion about 4000 of the general public were present, ranged round a central area in which the manœuvres were carried on. These consisted of the resuscitation of the apparently drowned, of those suffocated in conflagrations, and the treatment of street accidents. Twelve squads of trained men, representative of the police, the tramway company, the railway companies, and several manufactories and works in Edinburgh, gave an admirable demonstration of stretcher drill and of bandaging and "splinting" in cases of injury. The Edinburgh fire brigade added greatly to the interest of the proceedings by an exhibition of life-saving apparatus, and succeeded to admiration in rescuing two victims from a supposed fire in the lofty rafters of the hall. One of their number demonstrated the safety of leaping into a stretched sheet from a height of over forty feet, coming down unharmed, amidst the enthusiastic applause of the audience, who had awaited the *dénouement* with breathless anxiety. Improvised stretchers and surgical dressings made from articles of ordinary costume were also demonstrated, and the excellent hand and waggon ambulances kept by the association for the benefit of the citizens were fully exhibited in action. A statement was made of the work done by the association, which shows it to be in a flourishing condition, and places to its credit a great deal of most useful activity.

THE EDINBURGH CITY JUBILEE OFFERING.

A meeting was held lately to consider the form to be taken by the Jubilee subscriptions now being raised in Edinburgh. After several consultations of an informal nature, it was decided that a medical charity should be inaugurated for the benefit of consumptives. At the public meeting convened to settle the question, it was decided that the charity should take the form of a permanent fund for supplying consumptives with medicines and delicacies at their own homes; not for building a consumption hospital, as was recently announced in a contemporary journal. The reasons assigned for deciding against the hospital were that the Edinburgh climate is such as to render such an institution of comparatively little service, whilst it is thought that the fund applied as above may be a source of great benefit. Bailie Russell, who is chiefly responsible for this decision, said at the meeting that this opinion largely obtained amongst the medical profession in the city. It is doubtful, however, whether it is so unanimously held as he seems to think, and it is not improbable that a *plébiscite* of the profession here would have shown a directly opposite result.

THE JUBILEE DAY.

The city of Edinburgh hold its jubilee holiday on Friday, the 17th; the chief illuminations, including a monster bonfire on Arthur's Seat, will, however, be postponed till the 21st, when the University also will celebrate the auspicious event. A torchlight procession of unprecedented grandeur is to be held by the students in the evening. During the day a commemoration service will be held in St. Giles' Cathedral, at which the University authorities will be present in robes of office, and at which the other leading corporate bodies of the city will attend.

Edinburgh, June 14th.

DUBLIN.

(From our own Correspondent.)

ROYAL COLLEGE OF SURGEONS.

THE Council, at a special meeting held last Monday, the 13th inst., passed a resolution that delegates from the Council should be appointed to confer with delegates from the Apothecaries' Hall, in reference to a conjoint scheme of examination between the two bodies. If the combination is carried out, the question naturally arises, What will the College of Physicians do under the circumstances? Will they retire from their present alliance with the College of Surgeons or not? There are many who say that if the College of Surgeons join the Apothecaries the Physicians will retire from the scheme between the two Colleges; but I differ altogether from this opinion, and believe that the College of Physicians will not be inclined to dissociate themselves from the College of Surgeons. And the reason may briefly be stated: because they can join no other body; and if they refuse, it is probable that coadjutor examiners will not be granted them by the General Medical Council, and if so, they will very soon disappear from the list of licensing corporations in Ireland.

RICHMOND LUNATIC ASYLUM.

The report of Dr. Conolly Norman, resident medical superintendent, for the past year is a very important one, and will well repay perusal. The admissions during the year amounted to 438, a number considerably higher than the average for the last ten years. The deaths numbered 159. A severe form of dysentery occurred during the later months of 1886, and up to the date of the report still continued to prevail in the institution. Dr. Norman, who was appointed to the asylum only last September, is of opinion, from an examination of the death registers of the asylum, and also from the prevalence of diarrhœa and dysentery during his year of office, that these zymotic diseases appear to be endemic in the institution. These diseases and erysipelas, which is rarely absent from the house, are usually due to defective sanitation, and he states that the sanitary condition of the asylum is deplorable. He adduces ample proof of this statement; but as the main points have some months since been already referred to in these columns, I shall not go into details. Several months ago I mentioned the chief defects in the sewerage; and it will be impossible, now that public attention has been directed to the matter, for the governors to shirk the subject any longer. The defects which undoubtedly exist must be rectified, and that without delay. I believe I am correct in stating that a very eminent sanitary engineer has inspected the institution and reported fully to the Board of Governors, and that he has corroborated in the fullest manner the statement of Dr. Conolly Norman as to the sanitary defects of the Richmond Lunatic Asylum.

ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.

The annual meeting of this Society was held last week, and from the report of the Council it seems that its financial state cannot be regarded as satisfactory. At the meeting the sum of £1154 was awarded for distribution, of which £110 was to medical practitioners, £946 to widows, and £98 to orphans. The Society obtained a sum of £55 15s., which was handed over by the Council of the Royal College of Surgeons, in accordance with a proviso in the will of the late Mr. Richard Carmichael.

A CENTENARIAN.

A widow named M'Ananey died last week at Enniskerry, co. Wicklow, in her one hundred and ninth year.

THE REGISTRARSHIP OF BIRTHS ETC. IN CRUSHEEN DISPENSARY DISTRICT: ENNIS UNION.

Dr. W. H. Hynes, medical officer of Crusheen dispensary district, was the registrar of births for his district, but some weeks since he was removed by the Registrar-General for Ireland for the alleged reason that he delayed answering his communications. A successor was appointed without any protest from Dr. Hynes, as, from a monetary point of view, the office was of little value; but, on consideration, he concluded that the question of his removal by the Registrar-General was one of very great importance to dispensary medical officers in Ireland. The gentleman appointed having resigned, Dr. Hynes applied for the post, and this application was received by the guardians some few weeks since. Having heard his explanation, the guardians unanimously passed a resolution to the effect that they considered the Registrar-General had exercised high-handed authority in removing Dr. Hynes in such a summary manner, and that, before such a course had been adopted, the matter should have been referred to them. They further asked the Registrar-General to reconsider the matter and reappoint Dr. Hynes, stating, at the same time, that the "unanswered communications" complained of by the Registrar-General were addressed to Dr. Hynes during his absence on leave. I am informed that the Registrar-General has refused to appoint Dr. Hynes, and that a person whom he selected for the appointment has declined to accept it. An official from the General Register Office, under these circumstances, was sent down from Dublin, where for the past ten days he has tried to get the registrarship accepted, but without success. So the matter stands, and at present there is no registration going on in the Crusheen district, which is rather a serious matter. Dr. Hynes and the guardians complain of the want of courtesy in not consulting them on the subject, and refusing to endorse their recommendation of Dr. Hynes as a competent official. If, as alleged, the appointment of registrar according to the Act of Parliament is vested in the local authority, I cannot see how the Registrar-General can make the appointment. The salary of the post is only about £4 per annum!

Dublin, June 14th.

PARIS.

(*From our own Correspondent.*)

MASSAGE IN FRACTURES.

DR. GEORGES BERNE made an interesting communication to the Société Médicale de l'Elysée on the treatment of certain fractures by massage. After showing the importance of a good venous and lymphatic circulation in fractured limbs, he insisted upon the necessity of keeping the joints in the neighbourhood movable and supple. It is particularly in fractures of the radius and fibula that massage is useful, the inferior epiphyses being supported as it were by natural splints in the shape of the contiguous bones. Where there is not displacement, extensive centripetal *effleurage*, commenced early in the treatment, will promote the absorption of the blood extravasated around the fracture. Von Mosengeil has shown that massage displaces effusions through the lymphatic network of the cellular tissue, and the same thing occurs when centripetal pressure is applied above the seat of fracture. The rapid retraction of the tendinous sheaths of the fingers when they are immobilised is a matter of common experience. Dr. Berne maintains that this accident, almost inevitable with the usual treatment, may be obviated by massage. He states that he was the first to investigate this point in the treatment of fractures of the fibula, which he has treated with complete success by massage for the last three years. In 1884 a patient with a fracture of the lower end of the fibula without displacement was treated by Dr. Coupard and himself in the following manner:—Massage was employed from the very first day, the limb being placed in a plaster *gouttière*, from which it was removed every two days for this purpose. After each sitting of a quarter of an hour the apparatus was reapplied. From the fifteenth day the apparatus was laid aside, and the patient was able to walk without difficulty. The limb was in no way atrophied, and all the movements of the tibio-tarsal and tarsal articulations were natural. The temperature was normal. Other cases in the wards of M. Duplay at the Lariboisière Hospital have shown that there exists no better treatment of fractures of the fibula than *relative* immobilisation in a movable plaster bandage and periodical massage. The mean duration of the treatment by this method is from fifteen to seventeen days, instead of thirty, an important point, especially in hospital practice. Dr. Berne is also an advocate for massage in fractures about the elbow and patella, but he urges the necessity of caution whenever there is displacement or wound of the integument. In all cases, however, he maintains that manipulations should be performed by an expert scientific masseur, never by the so-called medical rubber.

SWEATING SICKNESS.

An epidemic of *suette miliaire* has reigned for some time past in several districts of the department of Vienne, principally in that of Montmorillon, but it has now spread to the surrounding country. At Bussière-Poite-Vinne, a village near Mezières, there are 250 cases amongst 2300 inhabitants, and more than twenty deaths have already occurred, some of them with extreme rapidity. A commission, consisting of MM. Chantemesse, Thoinot, and Descoust, has been sent by the Government to investigate the matter, and M. Brouardel has also gone for the same purpose.

PASTEURIANA.

The *Bulletin Médical* publishes a letter addressed by M. Pasteur to the Imperial and Royal Society of Vienna with reference to Dr. von Frisch's strictures on his method, and the comments thereon of Professor Billroth. M. Pasteur points out that the experiments performed by Dr. von Frisch, the results of which were unfavourable to his method, were made chiefly upon rabbits. He discusses their value, and concludes that "these facts not only ruin the experiments in question, but shake all confidence in the whole work of Dr. von Frisch. We must conclude either that Dr. von Frisch is a bad operator, or else that he allowed the virus, which he obtained in Paris, to become deteriorated." At the last meeting of the Vienna Society, reported in the *Semaine Médicale*, Dr. von Frisch went over the same ground as in his previous communication. He maintained that M. Pasteur's reply was not a refutation of his objections, and said that he was confident the future would decide in his favour. M. Ullmann, on the other hand, submitted three provisional conclusions to the Society, which were as follows: 1. Animals do not become rabid by inoculation with the preventive virus. 2. Some animals can be made refractory to rabies by the preventive inoculations. 3. The statistics of the preventive inoculations made (by M. Ullmann) in man appear favourable to Pasteur's method.

Paris, June 15th.

Obituary.

W. A. B. McCABE, F.R.C.S.

WE regret to record the death of this promising young surgeon, which took place at Sydney on April 18th, at the early age of twenty-five. He was born in Jersey, and received his early education at the Victoria College, St. Heliers. In 1879 he entered in the Faculty of Science of University College, London, and a year later, after passing the Preliminary Scientific Examination with honours, he commenced medical study. After a successful career as a student, he obtained the post of house-surgeon to University College Hospital in 1885, and at the commencement of the following winter session he was appointed Assistant Demonstrator of Anatomy in the College. This post he was obliged to relinquish on account of failing health after holding it for one year. As the winter advanced the symptoms of phthisis became more marked, and he was advised to take a voyage to Australia. Unfortunately severe hæmoptysis came on when he was near the end of the voyage, and he landed at Sydney almost in a dying state. Mr. McCabe was characterised in all he did by a conscientious and honest desire to do his best, and to his unsparing devotion to his duties may in part be attributed his early death. He was a good anatomist and a popular teacher. His genial character endeared him to all who knew him, and his abilities and enthusiasm gave promise, had his life been spared, of a brilliant career in the profession he had chosen.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.—The following gentlemen have recently passed the examination for the licence of the College:—

J. J. Jackson, L.R.C.S. Irel. | A. J. Tomkins, M.R.C.S. Eng.
R. F. McArdle, L.R.C.S. Irel.

COLLEGE OF PHYSICIANS IN IRELAND.—At the June examinations the following obtained licences in Medicine and Midwifery of the College:—

MEDICINE.—Patrick Joseph Barry, Edward Joseph Brady, Stafford Mouritz Cox, John Smyth Crowe, Edwin Tyrrell Cummings, Albert Edward Dyas, Richard Langford Fitzgerald, John Alexander Foreman, Henry Gell, Albert William Gray, Herbert Lennard Hudson, Edward Julian Jacob, Augustus Graydon Johnston, Joseph Christopher Lavertine, Francis James McArdle, Patrick Joseph Molony, John Brooke Moore, Neal Nelson, Richard Pennefather, Horatio Edward Rawlings, Edmund Boys Russell, John Stewart, Francis James Spilsbury, Ebenezer Teichelmann, William Hall Torbock, Patrick Joseph Ward, Edward Henry Wheeler.

MIDWIFERY.—Patrick Joseph Barry, Edward Joseph Brady, John Smyth Crowe, John Alexander Foreman, Henry Gell, Albert William Gray, Augustus Graydon Johnston, Neal Nelson, Richard Pennefather, William Hall Torbock, Thomas Torney, and Edward Henry Wheeler.

A special examination will be held on the 24th inst. and following days.

UNIVERSITY OF CAMBRIDGE.—At a congregation held on the 9th inst., the following gentlemen were appointed examiners:—

MEDICINE.—Dr. Norman Moore, St. Catherine's; Dr. Donald Mac Alister, St. John's; Dr. W. H. Broadbent, London.

MIDWIFERY.—Dr. A. L. Galabin, Trinity; Dr. W. O. Priestley, Edinburgh.

SURGERY.—Mr. G. E. Wherry, Downing; Mr. Charles N. Macnamara, F.R.C.S., Mr. Alfred Willett, F.R.C.S.

Also the following degrees were conferred:—

MASTER OF SURGERY.—Henry Walter Pigeon, Christ's.

BACHELORS OF MEDICINE.—Roger Neville Goodman, Hugh Richard Jones, St. John's; Henry Alfred Haviland, Pembroke; James Black, Sidney Blake Jolly, Gonville and Caius.

BACHELORS OF SURGERY.—Hugh Richard Jones, St. John's; Charles Silvester Evans, Clare.

SOCIETY OF APOTHECARIES.—The following gentlemen, having satisfied the Court of Examiners as to their knowledge of the Science and Practice of Medicine, Surgery, and Midwifery, received certificates entitling them to practise as Licentiates of the Society on June 9th:—

Bence, Frederic Herbert, Lancaster-road, Notting-hill.
Bloomer, Frederick William, Russell-street, Wednesbury.
Carter, John George, Brixton-road.
Clifford, Thomas, Thornhill-terrace, Sunderland.
Cockill, William Baron, Trittiville-gardens, Uxbridge-road.
Dodd, George Herbert, Rush-court, Wallingford.
Raby, Leonard, Southwold-road, Clapton.
Richards, George Frederick, The Firs, Beckenham-road, Penge.
Sandoe, John Worden, Bodmin, Cornwall.
Wakefield, Robert Clark, Ladbroke-grove-road, Notting-hill.

THE annual distribution of prizes to the students of the Bristol Medical School took place on the 7th inst.

VACCINATION GRANT.—Mr. F. M. D. Swallow, of the Silkstone District of the Penistone Union, has been awarded the Government grant for efficient vaccination.

BEQUESTS.—The City of Dublin Hospital has received £200 under the will of the late Mr. William Bannon, and £100 from Mr. Richard Kemmis.

THE prizes gained during the past summer and winter session at St. Thomas's Hospital were distributed to the successful competitors by Sir Henry Acland on the 15th inst.

AT the fourth annual meeting of the supporters of the Paddington Children's Hospital on the 10th inst., the financial position of the charity was reported to be very satisfactory.

VACATIONS OF RESIDENT MEDICAL OFFICERS.—The administration of the Assistance Publique in Paris has ordered that the *internes* (house-surgeons and house-physicians) of the various hospitals shall not take their holidays at the same times as their respective chiefs.

PRESENTATION. — Thomas Lamont Macartney, L.R.C.P. and L.R.C.S. Edin., has, on his leaving Worthen, been presented with a magnificent dining-room marble clock and figure, an illuminated address, and a purse of gold by a few of his friends and grateful patients in and around that district.

THE Duke of Portland will preside at a festival dinner, to be held at the Hôtel Métropole to-day (Friday), in aid of the funds of the West End Hospital for Paralysis and Diseases of the Nervous System.

AT the annual general meeting of the subscribers to the Queenstown General Hospital on the 7th inst. satisfactory financial and general reports were presented and adopted.

THE Water Committee of the Sheffield Corporation have come to an arrangement with the directors of the local water company under which the Corporation will take possession of the reservoirs, &c., next January.

THE Liverpool Marine Biology Committee has received a Government grant of £25 towards the expenses of the exploration of Liverpool Bay and the determination of its flora and fauna.

MEDICAL MAGISTRATE.—Colonel Pearson R. Cresswell, F.R.C.S., commanding the 2nd Glamorgan R.V., and Chief Surgeon to the Dowlais Iron Works, has been placed upon the Commission of the Peace for the County of Glamorgan.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.

FIRST EXAMINATION.

PART I.—CHEMISTRY, INCLUDING CHEMICAL PHYSICS.

Candidates must answer at least four questions, and not more than six. At least one question in each Section must be answered. Candidates unable to answer four questions must report the fact to the Presiding Examiner, and are not allowed to proceed with their examination.

Section I.—1. Explain clearly the construction of the ordinary mercurial barometer. Why does the mercury fall on ascending heights? What is understood by the term "boiling-point," and what is the connexion between the boiling of liquids and the atmospheric pressure? 2. What is understood by "conduction" and "insulation" as applied to electricity? Describe an electrical machine for frictional electricity, and make clear the objects of conduction and insulation in the machine. How would you proceed to electrify a person with positive electricity?

Section II.—3. Show by equations the result of the action of sulphuretted hydrogen upon the following bodies in solution: chlorine, sulphurous acid, ferric chloride, sulphate of copper, and ammonia. 4. Give two methods for the preparation of sulphur dioxide, and explain the bleaching effect of this acid and that of chlorine. 5. A piece of pure silver is dissolved in nitric acid. Describe the preparation from this solution of lunar caustic, of chloride, and of oxide of silver. Give the properties and formulæ of these bodies.

Section III.—6. How may urea be prepared from the urine? What is its composition and its formula? How do you account for the presence of carbonate of ammonium in stale urine? 7. Describe different methods by which starch can be converted into grape-sugar. How is this sugar distinguished from cane-sugar, and how is it detected in a solution? 8. Describe the preparation and composition of ordinary aldehyde. What are its leading properties? How is chloral hydrate prepared? What is its composition, and how is it related to ordinary aldehyde?

PART II.—MATERIA MEDICA AND PHARMACY.

1. Give an account of the action of digitalis. What are the doses of this drug and of its preparations? 2. What are the official compounds and preparations containing arsenicum? Give the strength of the preparations and the doses of all. What is the action of arsenious acid? 3. Give the preparations of ergot, colchicum, and ipecacuanha, and the composition of the pulvis ipecacuanhæ compositus and pilula ipecacuanhæ cum scillâ. Mention the composition, strength, and dose of the hypodermic injection of ergotin. 4. Give a description of (*a*) chloroform, (*b*) iodoform, and an account of the action of each. Enumerate their preparations, and mention the doses of those used internally. 5. Describe the action of the following sulphates: sulphate of iron, magnesium, quinine, sodium, zinc; and give the dose of each. 6. What is the source of pilocarpine? Give an account of its action. How would you administer it, and in what dose?

PART III.—ELEMENTARY PHYSIOLOGY.

1. How would you recognise under the microscope (*a*) the varieties of muscle, (*b*) a medullated nerve-fibre? 2. How does plasma differ from serum, and how may each be obtained from blood? 3. What is the composition of the atmosphere? How does expired differ from inspired air? What are the chief changes produced in the blood by respiration? 4. What are the chief constituents and uses of the gastric and pancreatic juices? 5. In starvation the body temperature is reduced. Explain this. 6. What is meant by (*a*) afferent nerve, (*b*) efferent nerve, (*c*) nerve centre? Give instances of their use.

SECOND EXAMINATION.

ANATOMY.

Candidates must answer at least four questions.

1. Enumerate the bony surfaces which form the anterior fossa of the base of the skull. What markings and foramina are there in this fossa, and what do those foramina respectively transmit? 2. Give the origin, course, and distribution of the external popliteal nerve and its branches. 3. Describe the origin, course, and distribution of the arteries which anastomose in the fossæ of the scapula. 4. Describe the dissection of the anterior part of the perineum down to the superficial layer of the triangular ligament. 5. Give the position, relations, connexions, and arterial supply of the stomach. 6. Give the origin, insertion, and nerve supply of the following muscles: (*a*) levator anguli scapulæ, (*b*) flexor sublimis digitorum, (*c*) rectus abdominis, (*d*) adductor magnus.

Digitized by Google

PHYSIOLOGY.

1. Describe the act of deglutition, including its nervous mechanism. 2. Describe the mucous membrane of the uterus. State the changes which occur at the menstrual period and during gestation. 3. Explain the effects of the respiratory movements on the circulation of the blood. 4. State and explain the effects of exercise on the excreta. 5. Describe the structure, action, and nervous mechanism of the iris. 6. Give the structure of adipose tissue. What is the chemical composition of the fats contained in it? From what constituents of food may fat be formed?

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

EXAMINATION FOR THE LICENCE.
(Third Part or Final.)

PRINCIPLES AND PRACTICE OF SURGERY.

1. Cancer of the tongue: give the symptoms, diagnosis, and treatment. 2. Give the symptoms, the possible results, and the treatment of syphilitic iritis. 3. Describe a case of congenital talipes varus, and give in detail the treatment that may be adopted. 4. What symptoms may be produced by the presence of a foreign body in the trachea or bronchus? How would you treat such an accident? 5. Senile gangrene: what are its causes, its usual course, and termination? What methods of treatment may be adopted? 6. Describe the symptoms and treatment of villous tumour of the bladder.

PRINCIPLES AND PRACTICE OF MEDICINE.

1. Describe the course of the transverse aorta. Give its anatomical relations, with special reference to the physical diagnosis of diseases of that portion of the arterial system. 2. Enumerate the symptoms usually met with in the third week of a case of typhoid fever, as they occur from day to day, and the remedial measures that you would adopt for their relief. 3. What are the signs of a pleural effusion on the right side, rising to the level of the third rib? What symptoms would make you come to the conclusion that the fluid was purulent? and, in the latter case, what treatment would you adopt? 4. Describe the pathology, symptoms, and treatment of infantile paralysis. 5. Describe the course of a case of unmodified small-pox, with its possible complications, especially noting its period of incubation (including its prodromal and eruptive stages), results, and proper treatment. 6. What are the symptoms of cancer of the stomach? Indicate the principal differences that would result from varieties of site in the morbid growth. How would you treat such a case? Write in full the prescription you would give.

MIDWIFERY AND DISEASES OF WOMEN.

1. Describe the chorion up to the end of the second month of gestation. 2. What are the causes of fœtal death in the last two months of gestation? 3. What are the chief methods employed for the induction of premature labour, and what are the circumstances which would determine the choice? 4. State fully what means should be adopted to prevent the occurrence of puerperal fever in obstetric practice. 5. Describe the varieties of cancer of the cervix uteri, with the diagnosis and pathology. 6. B——, aged thirty, was confined two years ago of her second child. She did not suckle the infant, and the catamenia reappeared one month after delivery. The periods, which were somewhat profuse, appeared regularly until a year ago, when the patient had a severe flooding. This recurred at irregular intervals until the time of her admission to the hospital a month ago. On examination, the uterus was felt to be slightly enlarged and the os uteri closed. What are the various conditions which may give rise to these symptoms, and what is the treatment?

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

DIPLOMA OF MEMBER.

PRINCIPLES AND PRACTICE OF MEDICINE.

Candidates must answer three of the four questions, including Question No. 4.

1. Give a full account of cancer of the stomach, including its orifices. 2. Describe the causes, diagnosis, and treatment of hæmoptysis. 3. Under what conditions is excessive elevation of the temperature of the body met with? What temperature is to be deemed dangerous, and what are the means whereby it may be reduced? 4. Give the composition, physiological action, medical uses, and doses of decoctum aloes compositum, ferrum redactum, lithiæ citras, liquor morphinæ hydrochloratis, apomorphinæ hydrochloras, pilula saponis composita, pulvis glycyrrhizæ compositus, syrupus chloral.

MIDWIFERY AND THE DISEASES OF WOMEN.

1. Describe the passage of a child through the pelvis with the breech presenting, with the sacrum to the right sacro-iliac synchondrosis. 2. State the circumstances in which convulsions come on in the puerperal state, and how would you distinguish between them? 3. State the means you would adopt with a view to prevent the infection of parturient and puerperal women. 4. A patient three weeks after labour has a painful fixed swelling in the left iliac fossa, with febrile symptoms. What is the probable nature of the swelling, and what course will it run?

SURGICAL ANATOMY AND THE PRINCIPLES AND PRACTICE OF SURGERY.

Candidates must answer at least four (including one of the first two) of the six questions, and are strongly advised to answer all six questions.

1. Describe the shape, position, and relations of the thyroid body. Mention particularly the points which would require attention in an operation for its removal. 2. Describe the arches of the foot, and the structures by which they are maintained, with especial reference to the deformity known as "flat-foot." 3. Name the most frequent dislocations and fractures occurring at the elbow-joint. Give their differential signs. 4. Describe the surgical treatment of empyema under its various conditions. 5. How may the production of lymph as the result of inflammation be accounted for? Describe its physical and chemical properties, and mention the changes it may undergo. 6. Describe the treatment to be adopted in a case of punctured wound of the cornea with prolapse of the iris. Mention the consequences which may ensue, and the proper modes of dealing with them.

MEDICAL NOTES IN PARLIAMENT.

Dog Owners Bill.

IN the House of Lords on the 10th inst. Lord Mount-Temple moved the second reading of the Dog Owners Bill, the object of which was to provide that the owner of a dog shall be liable in damages for any personal injury done by such dog to any person, and it shall not be necessary for the person suing for the recovery of damages for any such injury to show a previous mischievous propensity in such dog, or that the owner knew or had notice of such mischievous propensity, or that the injury complained of was attributable to any negligence on the part of the owner of the dog in the keeping or management of such dog.—The Lord Chancellor opposed the Bill, and the second reading was negatived.

Rabies in Dogs.

On the 14th inst., on the motion of Viscount Cranbrook, the following were nominated as the Select Committee on rabies in dogs:—The Lord President (Viscount Cranbrook), the Duke of Beaufort, the Earl of Coventry, the Earl of Carnarvon, the Earl of Onslow, the Earl of Zetland, the Earl of Kimberley, Lord Walsingham, Lord Ribblesdale, Lord Poltimore, Lord Belper, Lord Mount Temple.

Sanitation in India.

In the House of Commons on the 13th inst., in reply to Mr. Kenyon, Sir J. Gorst said that the sanitary condition of towns and villages in India was constantly under consideration by the Government of India and the Secretary of State, and that every effort had been, and would be, made to introduce from time to time such improvements as may be practicable.

Scarlatina Infection.

Lord John Manners stated, in answer to Sir U. Kay-Shuttleworth, that the investigations which the veterinary officials of the Agricultural Department had been instructed to make into Dr. Klein's theory of scarlatina infection from the milk of diseased cows were still being carried on, and the report would be laid before Parliament.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BEATLEY, WM. CRUMP, M.D. Durh., M.R.C.S., has been appointed Honorary Physician to the Newcastle-upon-Tyne Dispensary, vice R. Young, M.A., M.D., resigned.

BLACK, ROBERT, M.D. Lond., M.R.C.S., has been appointed Assistant Surgeon to the Sussex County Hospital, vice Uhthoff, resigned.

BRADBROOK, WILLIAM, M.R.C.S., L.S.A., has been appointed Medical Officer for the Inkberrow District of the Alcester Union.

CALDER, AUGUSTUS B., M.B., C.M.Ed., has been reappointed Visiting Medical Officer to the Perth Infirmary.

CLARKE, ARTHUR C., L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer for the Chipping Warden District of the Banbury Union.

EVANS, C. W., M.B. Lond., has been appointed Medical Officer of Health to the Bakewell Urban Sanitary Authority.

GILLARD, RICHARD, M.R.C.S., L.S.A., has been appointed Medical Officer for the Ugborough District of the Totnes Union.

GOWANS, W. BRUCE, M.B., C.M.Ed., has been appointed District and Dispensary Surgeon to the Perth Infirmary, vice Hunt, promoted Visiting Medical Officer.

GRAHAM, J. T., M.D. Glas., M.R.C.S., has been reappointed Visiting Medical Officer to the Perth Infirmary.

HEGARTY, ANDREW, M.D., M.Ch.Q.U.I., has been appointed District Medical Officer for the Draperstown Dispensary, vice Morewood, deceased.

HONNYWILL, ALFRED O., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer to the Lea Hall Branch of the Essex County Asylum, vice W. T. Davey, M.D., M.R.C.S., L.S.A., deceased.

HUGHES, ALFRED W., M.B., C.M.Ed., M.R.C.S., has been appointed Medical Officer for the Flint District of the Holywell Union.

HUST, LEIGH, M.B., C.M. Glas., has been appointed Visiting Medical Officer to the Perth Infirmary.

JEPSON, EDWARD, M.R.C.S., L.S.A., has been appointed Medical Officer for the Workhouse of the Durham Union.

KELLY, MICHAEL F., L.F.P.S. Glas., L.A.H., has been appointed Medical Officer for the Heworth District of the Gateshead Union.

KELSON, W. H., M.R.C.S., has been appointed House-Physician to the London Hospital.

MELSON, GEORGE HYDE, M.B. Lond., M.R.C.S., House-Surgeon to the Queen's Hospital, Birmingham, has been appointed House-Physician, vice Wm. Richards, M.B.Ed., resigned.

MORGAN, WILLIAM V., M.B., C.M. Aber., has been appointed Medical Officer for the First District and the Workhouse of the Narberth Union.

O'NEILL, J. GOWER, L.R.C.P., L.R.C.S., has been appointed Assistant House-Surgeon to the Rotherham Hospital.

POOLEY, THOMAS A., has been appointed Analyst for the Liberty of Havering-atte-Bower in the County of Essex.

RICHARDS, WILLIAM, M.B., C.M. Ed., has been appointed Resident Surgeon to the Birmingham General Dispensary, vice T. E. Gordon, M.D., M.R.C.S., resigned.

ROBERTS, GEORGE A. E., M.R.C.S., L.S.A., has been appointed Medical Officer for the Fourth District of the New Winchester Union.

SHIPTON, ARTHUR, F.R.C.S.Ed., L.S.A., has been appointed Medical Officer for the Buxton District of the Chapel-en-le-Frith Union.

THOMAS, JOHN, M.R.C.S., L.R.C.P. Lond., has been appointed House-Surgeon to the London Hospital.

THOMPSON, MAITLAND, L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer for the Fifth District of the Lincoln Union.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

CLINICAL HOSPITAL FOR WOMEN AND CHILDREN, Park-place, Manchester.—House-Surgeon. Salary £80 per annum, with apartments and board.

COVENTRY AND WARWICKSHIRE HOSPITAL. — House-Surgeon. Salary £100 per annum, with board (exclusive of beer, wine, and spirits), lodging, and attendance.

DURHAM COUNTY HOSPITAL.— House-Surgeon. Salary £100 a year, with board and lodging.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.—Assistant Physician.

HOSPITAL FOR WOMEN, Soho-square, W.—House-Physician. Salary £75 per annum, with board &c.

LIVERPOOL DISPENSARIES.—Assistant Surgeon. Salary £80 per annum, with apartments, board, and attendance.

NATIONAL DENTAL HOSPITAL AND COLLEGE, Great Portland-street, W.—Anæsthetist.—Lecturer on Operative Dental Surgery.

ST. LUKE'S HOSPITAL. — Resident Clinical Assistant. Board and residence.

WESTMINSTER GENERAL DISPENSARY, Gerard-street, Soho, W.—Honorary Surgeon.

WESTMINSTER HOSPITAL, Broad Sanctuary, S.W.—Surgical Registrar. Salary £40 per annum.—Assistant Surgeon.

WESTERN OPHTHALMIC HOSPITAL, Marylebone-road, W.—Dispenser.

Births, Marriages, and Deaths.

BIRTHS.

DAWSON.—On the 14th inst., at Heathlands, Southbourne-on-Sea, the wife of Yelverton Dawson, M.D., of a daughter.

MACKENZIE.—On the 14th inst., at Finsbury-square, E.C., the wife of Stephen Mackenzie, M.D., F.R.C.P., of a son.

SCANLAN.—On the 8th inst., at Springfield, Pembroke, the wife of Surgeon-Major Scanlan, Army Medical Staff, of a son.

SCOUGAL.—On the 13th inst., at Brooklands, Gledholt-road, Huddersfield, the wife of E. F. Scougal, M.A., M.B., of a son.

SKIPPER.—On the 12th inst., at Tollington-park, N., the wife of Edward Skipper, M.D., of a daughter.

MARRIAGES.

ALLEN—MAIR.—On the 11th inst., at Holy Trinity Church, Hastings, Surgeon-General F. F. Allen, C.B., and Q.H.P., to Florence Mary Jane, third daughter of George J. J. Mair, Esq., F.S.A., of Upper Bedford-place, Russell-square, London.

ARCHER—COMMERFORD.— On the 14th inst., at St. John's, Hackney, by the Rector, the Rev. A. Brook, M.A., Launcelot Archer, M.R.C.S., of 38, Vincent-square, Westminster, eldest son of Thomas Archer, Esq., of Clapton, to Susie, only daughter of N. W. Commerford, Esq., of Clapton-square.

HATCH—HOMAN.—On the 4th inst., at St. Marylebone Church, William Keith Hatch, M.B., F.R.C.S., Bombay Medical Staff, to Clara Catherine, third daughter of S. A. Homan, Esq., Deputy Surgeon-General, Indian Army (retired).

MACKENZIE—CHRISTIE. — On the 15th inst., at St. Mark's Church, Surbiton, by the Venerable Archdeacon Burney, assisted by the Rev. A. H. Murray, Surgeon A. W. Mackenzie, 5th Punjab Infantry, Punjab Frontier Force, to Jessie Thompson, eldest daughter of the late John Christie, of Forth-bank, Stirlingshire.

MILES—KING.—On April 28th, at All Saints' Church, St. Kilda, near Melbourne, Victoria, by the Rev. J. H. Gregory, Incumbent, assisted by the Rev. Horace Tucker, Incumbent of South Yarra, Melbourne, George Edward Miles, L.R.C.P., M.R.C.S., of Callan-park, Sydney, N.S.W., to Ada Louise, youngest daughter of the Rev. Richard King, of Hampstead, late of Prestwich, Manchester.

PRESTON — SADLER. — On the 9th inst., at St. Mildred's Church, Canterbury, by the Rev. J. Parmiter, Rector, assisted by the Rev. R. N. Gandy, Rector of St. Andrew's, Canterbury, and the Rev. T. Preston, Vicar of Swaffham Prior, Cambridge, father of the bridegroom, Henry Octavius Preston, M.R.C.S., to Dora Mary Sadler, only child of Henry George Sadler, of Oswald House, Canterbury.

DEATHS.

CAMERON.—On the 11th inst., at Morefield, Aberdeen, William Hector Cameron, M.R.C.S., late Staff Surgeon, R.N.

GLOVER.—On the 8th inst., at St. Thomas's Hospital, John Philip Glover, M.R.C.S., L.R.C.P., M.D.Lond., late of Quarndon, Derbyshire, aged 41.

LAUDER.—On the 4th inst., at Comely Bank, Tayport, Fife, Robert Scott Lauder, M.D., aged 43.

MCCABE.—On April 18th, at Sydney, William Alexander Bowes McCabe, F.R.C.S., aged 25.

OXLEY.—On the 14th inst., at Llandudno, Martin Gay Black Oxley, M.D., aged 46.

N.B.—A fee of 6s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

SITES FOR INFECTIOUS HOSPITALS.

Mr. G. L. Purchase.—In answer to an inquiry involving the question as to what is the proper area for the site of an infectious hospital, we would point out that for the permanent requirements of an ordinary district arrangement should be made for so placing beds, at the rate of 1 per 1000 of the population, on the site that the number of beds shall not exceed twenty per acre. It may not be deemed requisite to make all the permanent provision at once; but, on the other hand, it is of the greatest advantage to acquire a site exceeding the present requirements and admitting of such temporary hospital extension as an epidemic might necessitate. In placing the buildings on the site an unoccupied zone of not less than forty feet in width should be provided between all buildings intended to receive infected persons and things and the boundary wall or fence. The administrative building ought to be kept free from infection, and it is customary to erect it near the boundary of the site in such a way that entrance to the premises may be effectually controlled from it. Other points relating to the selection of hospital sites will be found in the Supplement by the medical officer to the Tenth Annual Report of the Local Government Board on the Use and Influence of Hospitals for Infectious Diseases.

Dr. G. Thomson (Oldham).—A list of coroners, medical and legal, will be found in Churchill's Medical Directory.

Mr. W. Habgood.—Such clothing can be obtained at 44, Fore-street, E.C.

"TO PASTURES NEW."

To the Editors of THE LANCET.

SIRS,—It should not be difficult to meet the modest requirements of your correspondent, "Emigrant." He desires simply a good climate, an out-door life, and the chance of making £100 a year. He has forgotten, however, to indicate the nature of his ill-health, which would be a material factor in modifying the advice to be given him. He can hardly be far wrong, however, in selecting one of the Australian colonies, and, apart from any personal considerations to guide his choice, probably Sydney affords about the best *locale* at present. If your correspondent dislikes heat, he might try Dunedin in New Zealand. The colonies afford the certainty of a good climate, and a fair prospect of a competency to an active man who can take the rough with the smooth. The sport, however, to which your correspondent alludes is not very first-rate in the colonies, as their legislators have omitted to copy one of our national institutions—viz., the Game Laws.

I am, Sirs, yours obediently,

Belfast, June 13th, 1887. J. A. L.

A WORM IN AN EGG?

Messrs. A. Kendrick and Co.—The specimen was in so dried a state when received that a precise determination of its nature could not then be made. We hope, however, to be in a position to report next week. Meanwhile it may suffice to say that there is no *primâ-facie* improbability against the entrance of intestinal parasites into an egg; for they are known to wander into the oviducts of birds. We may refer to THE LANCET, 1849, vol. ii., p. 386, where a correspondent forwarded us a specimen of ascaris lumbricoides which had been found in a newly laid egg.

Dr. McNalty.—Most of the treatises on surgery discuss the subject. Our correspondent might refer to the article "Nævus" in Heath's Dictionary of Practical Surgery.

Mr. Harvey (Ottawa).—We cannot exchange.

"SWEATING OF THE FEET."

To the Editors of THE LANCET.

SIRS,—I have seen only two cases of sweating of the feet. The first was a gentleman who had some years before suffered from syphilis. He was accustomed to the morning tub and other necessary sanitary customs of society, but a few days' hard walking on pavements had rendered his society intolerable owing to the offensive smell from his profusely perspiring feet. His sufferings were enhanced by the raw state this condition had induced. I ordered his socks to be changed night and morning, and the feet to be first washed in cold water with carbolic soap and dried, and next swabbed all over with a lotion made by adding a drop of liq. atropiæ to an ounce of liq. hydrarg. perchlor. This to be allowed to dry on by evaporation. In thirty-six hours I found him quite well, and making preparations to go into camp, he being a volunteer. He has since, I believe, had no return of the annoyance. The second case was that of a servant girl. Her feet were less offensive than were those of the gentleman in the former case, but very painful. Similar treatment quickly cured her.

I am, Sirs, yours faithfully,

Skipton-in-Craven, June 11th, 1887. C. W. SESSIONS BARRETT, M.B.

THE MEDICAL PROFESSION AND JUBILEE HONOURS.

A CORRESPONDENT, under the *nom de plume* of "Brackenthwaite," has sent us a communication in favour of the granting of a peerage to a member of the medical profession, and the bestowal upon the Army Medical Staff of honorary rank. The fact that our correspondent's letter has already appeared in a contemporary, above the signature of "B," prevents us allowing it to appear in our columns.

Mr. R. Saunderson.—The title "physician" attaches to an associate of a College of Physicians, and cannot be claimed or used satisfactorily on the strength of the qualification mentioned in our correspondent's letter. A L.S.A. or L.A.H. is a licensed and qualified medical practitioner.

Mr. E. F. Le Souef.—So far as we are aware, the gas has not been employed in the way and for the purpose named.

CHINESE PHARMACOLOGY.

To the Editors of THE LANCET.

SIRS,—In my "Contributions to Materia Medica and Natural History of China" (1871, Trübner) I have endeavoured to provide something like an Anglo-Chinese dispensatory. Dr. Dobson, in his "Medical Vocabulary in English and Chinese" (Shanghai Mission Press, 1858), on page 59, gives several "names of medicines," and I have followed him as much as possible. The terms and names have had to be manufactured, and I have endeavoured to convey by sense and sound some idea (to the Chinese) of the thing indicated. Iodide of potassium I have called *hai-tien sha*, literally, "sea-indigo salt." Iodine is, of course, obtained from the ashes of sea-weed, and the colours are near enough to each other. I should be happy to associate myself with any Chinese scholar, in order to bring about uniformity in the use of medical and pharmaceutical terms in Chinese.—I am, Sirs, faithfully yours,

Shepton-Mallet, June 8th, 1887. F. PORTER SMITH.

THE DIURETIC ACTION OF MERCURIALS.

G. B. (Paisley).—The most recent authority on the subject is Rosenheim of Berlin, who has worked in concert with Fürbringer. He finds that calomel is contra-indicated in parenchymatous nephritis, while, on the other hand, it has a safe diuretic action in interstitial nephritis. Of the other preparations of mercury, the yellow iodide has also given good results in this form of renal mischief, but not so invariably as calomel. The bichloride of mercury, like the grey mercurial ointment, produces diuresis, but comparatively slight and of brief duration.

Dr. Rowe (Basutoland).—According to the last published returns of the Registrars-general for the several parts of the United Kingdom, the proportion of males to females born in England and Wales was 103·9 to 100 in the year 1886; in Scotland the proportion was 105·4 to 100 in 1883; and in Ireland it was 105·3 to 100 in 1885.

Querens.—The question is still undecided.

CHEMICO-LEGAL ANALYSES IN CUBA.

THE Royal Academy of Sciences of Havana has presented a memorial to the Governor General of Cuba, calling his attention to the extremely unsatisfactory and expensive way in which chemical analyses for medico-legal purposes are now carried out in the island, and praying that steps may be taken to establish an institute of chemico-legal examinations similar to the institutes recently established in Spain. The memorial states that the chemical examinations, which are now mostly conducted by pharmacists acting under the authority of the magistrates, cost the State at least about $30,000 annually, and that as the number of analyses required is rapidly increasing, there is no doubt that the sum of $120,000 will very soon be absorbed. This immense sum, while acting as a heavy burden on an already impoverished treasury, does not afford any guarantee that the analyses are conducted in a trustworthy manner, many of the analysts having a very imperfect acquaintance with chemistry, and the good faith of a certain number of these so-called experts not being above suspicion. It is suggested that for the sum of about $12,000 annually a really efficient institute could be maintained, under the charge of a competent chemist with a salary of $3000, and two assistants—a pharmacist and a medical man—each with $2500. An attendant would receive $500, and the cost of materials is estimated at $2500. Certainly, if the state of forensic chemistry is as unsatisfactory as the Royal Academy believes, it is high time some better system were adopted; and the proposed institute, which would be a sort of Somerset House laboratory, seems a fair method of meeting the want.

Junta.—We think the statement one of the most incredible we ever read, though, of course, we receive it on the strength of our correspondent's authority. The duty of the lady and her husband was peremptorily to stop and decline such obtruded services, and to make the practitioner understand that his visits would not be allowed.

Surgeon.—The office of the Crown Agents for the Colonies, Downing-street, S.W.

TREATMENT OF POISONING BY CHOKE-DAMP.

To the Editors of THE LANCET.

SIRS,—Recently a serious accident happened at, or near, Hamilton, and the following is taken from the report of the accident, which appeared in the *Scotsman* of May 30th:—"The more seriously injured were carried into sheds and other places at the pit-head, where Dr. Robertson, who was at that time alone, attended to them. Fifteen of them required his attention for the effects of choke-damp, they being more or less asphyxiated, some of them, indeed, to an extent that was exceedingly alarming. Half a dozen small pits had been dug by the medical officer's orders, and the men were laid with their heads just over the edge of these, in order that as the poisonous gases were exhaled from the lungs they might be absorbed by the fresh earth, which possesses a sufficient quantity of oxygen to change their character. In one or two cases artificial respiration was also deemed necessary."

Many of your readers would no doubt be glad of an explanation of the above treatment.

I am, Sirs, yours truly,

June, 1887. AMBULANCE.

THE BROWN DEFENCE FUND.

To the Editors of THE LANCET.

SIRS,—Kindly insert the following:—Amount already acknowledged, £24 1*s.* 6*d.*; Messrs. Oram and Read, £1 1*s.*; Dr. A. W. Thomas, 10*s.* 6*d.*; Dr. E. Adams (Liverpool), 5*s.*

I remain, Sirs, yours faithfully,

G. STANLEY MURRAY, M.D.

23, Upper Richmond-road, Putney, June 14th, 1887.

CALCULUS IN CHINA.

THE *China Medical Missionary Journal* asks: "Is stone in the bladder anywhere so common as in Kwangtung, where, since the first lithotomy by Dr. Parker at the Canton Hospital in 1844, to the end of 1885, no less than 1057 cases have been operated upon by lithotomy and lithotrity, exclusive of a large number of urethral and preputial calculi extracted? Is it so prevalent in Corea as reported some time since; and what is known of the potent dissolvent of the native physicians there, which potion 'relieved in a few hours, after long and terrible sufferings,' the French Missionary Bishop Ferreol, about 1850?"

ERRATA.—Owing to unavoidable delay in the return of the proof of Sir Andrew Clark's Cavendish Lecture two or three errors escaped correction:—In line 16 of second paragraph the "l" was omitted from the word "causality"; para. 6, line 4, the name "Morell" should have preceded "Mackenzie"; para. 7, line 20, for "assuredly" read *probably;* same para., line 28, for "useful" read *useless;* para. 8, line 13, after "followed" insert "it is said"; para. 9, last line, for "wherewith" read *whereby;* para. 10, line 15, for "arsenic hydrochloric" read *hydrochlorate of arsenic;* para. 11, line 4, for "a thousandth" read *two-thousandth.*

Medical Diary for the ensuing Week.

Monday, June 20.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesday, 2.30 P.M.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.

Tuesday, June 21.

GUY'S HOSPITAL.—Operations, 1.30 P.M. and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M.

Wednesday, June 22.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesday and Thursday, 1.30 P.M. Surgical Consultations, Thursday, 1.30 P.M.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; Friday, 2 P.M.; Saturday, 1 P.M.
CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9 A.M.; Saturday, same hour.
BRITISH GYNÆCOLOGICAL SOCIETY.—8.30 P.M.—Specimens will be shown by Dr. Francis Imlach, Dr. Fancourt Barnes, Mr. Lawson Tait, and others.—Dr. A. V. Johnstone (Danville, Kentucky): The Endometrium in the Cycle of the Rut. Council at 8 P.M.

Thursday, June 23.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Ophthalmic Operations, Friday, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8 P.M. Mr. Lockwood: Specimens illustrating the Anatomy of the Capsule of Tenon.—8.30 P.M. Collection of Evidence regarding Toxic Amblyopia. Communications will be made by Messrs. Nettleship, McHardy, Edgar Browne, Hill Griffith, Frost, Juler, Shrears, Morton, Gunn, and others.

Friday, June 24.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

Saturday, June 25.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year ..... £1 12 6 | Six Months £0 16 3
To CHINA AND INDIA ..... One Year 1 16 10
To THE CONTINENT, COLONIES, AND UNITED STATES ..... Ditto 1 14 8

Post Office Orders should be addressed to JOHN CROFT, THE LANCET Office, 423, Strand, London, and made payable at the Post Office, Charing-cross.

Notices of Births, Marriages, and Deaths are charged five shillings.

Cheques to be crossed "London and Westminster Bank."

Clinical Lecture
ON
FUNCTIONAL DISEASES OF THE LIVER.

BY SAMUEL FENWICK, M.D., F.R.C.P.,
PHYSICIAN TO THE LONDON HOSPITAL.

(*Concluded from page 1220.*)

YOU are aware that the condition of the system producing acute rheumatism has been a fertile subject for discussion, and that numerous attempts have been made to discover it both by chemical analysis and by experiments on animals. Now, it will naturally occur to you to ask whether we may not have hit upon the cause of the disease in the excess of the sulphocyanide present in the saliva of such cases. I fear that we are unable to answer this question in the affirmative; for, as we have before seen, the salivary salt is augmented in various other conditions that are unattended with articular inflammations. Besides, if the cause of the rheumatic fever were dependent on the presence of this salt in the system, we should expect to find it in greater quantity when the disease was hereditary that when it occurred in a single member of a family alone. To ascertain if such is the case I have added the following table.

TABLE X.—*Showing the average amount of Sulphocyanide in persons hereditarily predisposed to Rheumatic Fever.*

—	Average amount of sulphocyanide.	No. of cases.
History of parents liable to rheumatic fever ...	+ 1·4	16
„ other members of family than parents liable to rheumatic fever	+ 1·65	10
Persons who had no history of rheumatic fever	+ 1·4	31

You will see by the above table that a hereditary predisposition has no effect in increasing the amount of the salivary salt, or consequently the severity of the attacks, for the average amount is the same in those whose parents had suffered from the complaint and in those from whom no history of hereditary predisposition could be obtained. It is also curious that previous attacks do not seem to increase the quantity of the sulphocyanide, for of twenty-four who had a history of former attacks the average was + 1·4, whilst in twenty-eight who were suffering for the first time it was + 1·3.

As there is a close connexion between the severity of the complaint and the state of the saliva, I would advise you in every case to watch the amount of sulphocyanide, and, whenever you find the salt in excess, to keep your patient on low diet and guard him carefully from cold and every other circumstance likely to provoke an attack. It is probable that those who have habitually a large amount of the sulphocyanide in the saliva are more liable to local rheumatism than other persons; for amongst the "private cases" 40 per cent. of those who had an excess had suffered from pains of the limbs or joints. This is not, however, so constantly the case as in acute rheumatism, for I have met with cases of lumbago and rheumatic arthritis in which the amount was below the normal.

The occurrence of chorea in rheumatic subjects has long been recognised, and has given rise to much speculation as to the connexion between diseases so very dissimilar. I felt anxious, therefore, to ascertain whether the examination of the saliva would throw any light upon this question. I find nine cases of chorea are recorded in the "later hospital cases," and of these, at the first observation, six presented an amount of sulphocyanide below the normal, some as low as − 3; two were normal; and only one was above the normal—viz., + ¼. One developed acute rheumatism, which affected both ankles, but lasted only one week, the evening temperature being 102° and 103°. The saliva for three weeks before the rheumatism occurred had risen to + 2, + ½, and + ⅓, being + 1 during the articular affection. Two other cases had a systolic mitral murmur, and in both the salivary salt was in excess; one was admitted with + ¼, but next week it rose to + 2¼, + 2, and + 2¼; the other, on first observation, showed − ¼, but next week it was + 2¾, then in the two following weeks + 3 and + 2½. None of those whose saliva remained below the normal had either rheumatism or mitral murmur. It is worthy of remark that the chorea in those in whom the excess presented itself yielded rapidly to treatment, whilst where it continued below the normal the complaint was very obstinate. Thus the two presenting an excess were dismissed on an average in thirty-seven days, whilst the three with a deficiency remained on the average seventy-seven days under treatment. It is strange that in chorea, unlike the diseases we have hitherto examined, there is always a tendency to great variation in the quantity of the sulphocyanide from week to week, very few of the cases showing the same quantity in any two successive observations. I have observed the same variation in the weekly amounts of sulphocyanide in some cases of hysteria, and suspect it may arise from an imperfect action of the nervous centres.

It is always unsafe to draw general conclusions from small numbers of facts, but, if future inquiries should confirm these above stated, it would appear that there is no necessary connexion between chorea and rheumatism, but that the latter is apt to arise whenever the imperfect nutrition which accompanies chorea is suddenly replaced by an excessive amount of vitalised nutriment. The long-continued subnormal amount of sulphocyanide is associated with a long duration of the nervous disturbance, and would seem to indicate that the treatment adopted was ineffectual. In one such case I lately omitted the arsenic the patient was taking, and substituted cod-liver oil and hypophosphite of soda. In a few days the salivary salt increased, and the patient so rapidly improved that she was soon discharged.

Cases of gout usually exhibit an increase of the salivary salt, but not to such a marked extent as those liable to acute rheumatism. In seventeen that were observed in the "private cases" the amount was above the normal, and none of them at any time presented a deficiency. When, however, gout has been complicated with phthisis or kidney disease, I have met with a subnormal quantity; so that the state of the saliva is clearly not the result of the articular inflammation, but is only an accompaniment of that over-action of the nutritive organs which most practical physicians are in the habit of recognising as predisposing to the complaint.

The sulphocyanide is usually in excess in the saliva of persons who suffer from eczema, as this is so often associated with gout; but such is not invariably the case, as the disease also presents itself in persons who are in an imperfect state of nutrition, and under these circumstances the salivary salt is below the normal.

I have never seen a severe case of urticaria in which the sulphocyanide was not in excess, and the severity and obstinacy of the malady may be generally measured by the amount of colour produced by the addition of iron to the saliva. As an illustration let me quote to you the case of a gentleman aged thirty-one. He was stout, and was affected with this troublesome complaint to such an extent that he was in the habit of amusing his friends by writing on his arm beneath the table with a match or pencil, and then exhibiting the letters marked in bright and elevated lines upon his skin. His saliva was + 3, but after six weeks treatment it was reduced to + ½; bilious headache, to which he had been formerly subject at least every week, disappeared, and he lost many pounds in weight.

Headache was one of the most common subjects of complaint to which those having an excess were liable, and the so-called "bilious headaches" constituted 25 per cent. of the whole number of the "private cases" where this condition of the saliva was present. Persons suffering in in this way usually belonged to families of which other members had been victims to gout or rheumatism; the attacks of headache were periodical, and were often followed by a temporary improvement in health. One-tenth of those presenting a deficiency of sulphocyanide also complained of "bilious headaches," but there was usually no gouty history, no relief was afforded by the attack, and the pain seemed to be of a purely neuralgic character. The importance of such a distinction in a practical point of view need not be pointed out, for it will be obvious that symptoms connected with such opposite conditions of the nutritive organs cannot be successfully treated in the same manner.

Digitized by Google

A great excess of the sulphocyanide, when it occurs in elderly persons, is often indicative of a dangerous condition of health, and may be for some time unaccompanied by apparent disease of any important organ of the body. Afterwards, however, changes in the vascular system usually declare themselves, and the patients eventually die of apoplexy or become the subjects of disease of the heart or kidneys. As an instance of this, a gentleman, aged fifty-nine, first complained in 1877 of irritability of the bladder, the urine being very acid, but neither albuminous nor saccharine. This soon passed away, and in the following year he suffered from shooting pains of his arms and shoulders, although he had never had gout or rheumatism previously. In 1881 he had bronchitis, and his saliva was then recorded to have contained a great excess of sulphocyanide. In the same year he suffered from intense mental depression and dyspepsia, the saliva still presenting a great excess. Towards the end of the year it was +4, and a diastolic murmur was first noticed over the aortic valves. This was followed by a slight paralytic attack. The loss of power soon passed away, the saliva rose quickly to +8, and he complained of general weakness and depression. In 1882 the saliva was +6, there was no paralysis, the diastolic murmur was still audible, but the urine proved to be slightly albuminous. He remained in this condition for a few months, when he was carried off by a sudden apoplectic seizure.

Cases like the above are by no means uncommon, and are subjects of great anxiety to the physician on account of the indefinite nature of the symptoms from which the patient suffers. They are generally said to arise from "suppressed gout," but I suspect that atheroma of the arterial system takes place from the abnormal nutrition, and produces changes in the blood supply of various important organs. I know of no test for such a state but the excess of the sulphocyanide, and I have found this almost always to be the case under such circumstances.

A deficiency of the sulphocyanide is much less common in persons enjoying a moderate share of health than the opposite conditions. It chiefly shows itself in females, and especially in those who are thin and feeble in muscular power. They seem to be especially liable to neuralgic affections, and as these also often arise from gout, rheumatism, or malaria, in which the sulphocyanide is in excess, an examination of the saliva will often throw light on the nature of a case otherwise hopelessly obscure.

We may now ask whether the foregoing facts and the conclusions we have derived from them throw any light upon the uses of the sulphocyanide in the saliva. Does this substance perform any beneficial purpose in the mouth or throat, or is it only an excretion, removed on account of some deleterious effects it might produce upon the system? Again, what is the material from which it is separated, and is this material broken up by the salivary glands, or is the sulphocyanide only an ultimate product of the action of a number of organs associated together in function? In answer to the first of these inquiries, we may assume that the sulphocyanide must be of use in assisting the functions of the upper part of the digestive tract, for we can scarcely suppose that any deleterious substance would be excreted in a part where there is a certainty of its being rapidly resorbed into the system.

Before attempting to settle the remaining questions, let us first examine two suggestions that have been made by physiologists to account for the presence of the salt in the saliva. It has been stated that it is the result of decomposition set up by the presence of decayed teeth, and that it is not therefore a normal constituent of the secretion, but is merely a pathological product. In order to test how far such an opinion was founded upon facts, careful inquiries were made into the state of the teeth in eighty-seven cases in the hospital, and with the following results. The teeth were quite perfect in 18 per cent. of those whose saliva contained a normal or excessive amount of sulphocyanide, and in only 14 per cent. of those in whom it was deficient. One or two teeth were carious in 47 per cent. of the former and in 44 per cent. of the latter; whilst many were decayed in 42 per cent. of those in whose saliva the sulphocyanide was below, and in 35 per cent. of those in whom it was normal or excessive. It is evident, therefore, as the salt presents itself in excessive quantities where there is no decay of the teeth, and is as often deficient as superabundant where many are carious, the opinion before mentioned must be incorrect.

Others have attributed the presence of the sulphocyanide to the smoking of tobacco, and the habits of two hundred and thirteen patients in the hospital were investigated as to this point. As the greater number had been confined to their beds in wards in which smoking was not allowed, only a few of them had latterly enjoyed the opportunity of using tobacco. On analysing these cases, it appeared that, of those whose saliva contained an excess of sulphocyanide, 6 per cent. had only latterly smoked; of those presenting a normal quantity, only 2 per cent.; whilst of those in whom there was a deficiency, 8 per cent. had latterly consumed tobacco, and one represented himself as an excessive smoker. It is therefore evident that no material influence is exerted by the use of tobacco, although my own impression before analysing these cases was that the salt is usually present in greater quantity in the saliva of those who smoke than of those who abstain from tobacco.

From the facts we have before considered, it is plain that an excess of the sulphocyanide is present in the saliva whenever the nutritive functions are in a state of unusual activity, and that a deficiency of this salt coincides with a defective supply of new material. As, however, a number of different organs co-operate in the preparation of the materials for the growth of the tissues, to which of these can we attribute the formation of the salivary salt? At first sight we might suppose it was the result of some chemical change connected with the gastric digestion, for its diminution in cancer of the stomach, stricture of the œsophagus or pylorus, atonic dyspepsia, and even frequent vomiting, seems to point in this direction. But, on the other hand, this will not explain its deficiency in cases of cirrhosis attended with ascites, or its sudden increase directly the pressure had been removed from the portal vessels by tapping, nor does it show why the quantity should be so often below the normal amount in jaundice.

A full supply of albuminous food is, however, necessary for a free secretion of bile, and for this purpose the conditions both for its digestion and absorption must be favourable. We before found that chronic diarrhœa and dysentery lessened the amount of the salivary salt, and it is interesting to observe that Dr. Rutherford, when reviewing the results of his experiments on the secretion of bile in dogs, states that "we have, however, found several drugs that have an indirectly depressant action; thus, when the intestinal glands are excited to secrete, there is an indirectly depressant effect on the liver, whereby the bile secretion is lessened. We invariably observed that while slight purgation by a purely intestinal irritant scarcely, if at all, depressed the secretion of the bile, powerful purgation produced a very marked effect."[1]

I have before pointed out that the sulphocyanide is either absent or in very small quantity in the saliva of persons affected with lead colic, but that as soon as the symptoms are relieved it reappears. Now, if we turn again to the experiments of Dr. Rutherford, we find the following remarkable statement: "It cannot fail to strike the reader as a remarkable fact, that while in the long list of drugs whose hepatic effect we have investigated we have found so many that stimulate the liver, there is only one—acetate of lead—which appears to have a directly depressant effect."

Physiologists are generally agreed that the main portion of the fat of the animal body is the result of the breaking-up of the albuminous material of the food by the liver, and in reviewing the "private cases" in which the condition of the saliva was tested, I find that only 6 per cent. in whom there was an excess of the sulphocyanide were thin; 20 per cent. were moderately stout, and 74 per cent. are recorded as fat. On the contrary, of fifty-three cases where the sulphocyanide was below the normal amount, forty are stated to have been thin, three as moderately stout, and only ten as stout. In some of the latter the deficiency of the salivary salt was only temporary, and of the remainder four were stated to have been losing flesh when the saliva was examined. But if we thus find the same circumstances that tend to promote a free secretion of bile also accompany an increase of the sulphocyanide, and the circumstances that lessen the formation of bile also diminish or suppress that of the salivary salt, and if we discover the condition of the body present in those whose saliva presents an excess and diminution of the salt such as

[1] Professor Rutherford on the Action of Drugs on the Secretion of Bile, p. 170.

Digitized by Google

we might expect from an increased or lessened activity of the liver, I think we are justified in connecting the presence of the salt in the saliva with the action of the hepatic cells.

I need not remind you that the bile is a complex secretion containing colouring matters, cholesterine, and biliary salts; now from which of these may we suppose the sulphocyanide is derived? Clearly not from the cholesterine, for this is excreted; nor from the colouring matters, for they also pass out of the body, and if they were the source of the salt in question, we should always find it in excess in cases of jaundice, as they are in that disease retained in the circulation. The remaining constituent of the human bile, the taurocholate of soda, seems to be the most likely source of the salivary salt, as it passes from the liver into the intestine and is resorbed into the circulation; for I think we can only account for the absence or diminution of the sulphocyanide in jaundice by supposing that the material from which it is produced passes in the normal state from the liver into the duodenum. This view is supported by the fact that in all the cases of dyspepsia accompanied by eructations of sulphuretted hydrogen gas which I have examined there was an absence of the sulphocyanide. In such instances, we may suppose that the biliary acids are decomposed in the duodenum into sulphuretted hydrogen, instead of undergoing their normal decomposition.

But a difficult question now meets us. The albuminous materials of the food absorbed from the digestive canal undergo certain changes which fit them for the purposes of nutrition, and the greater part of these are again broken up into urea and carbonic acid, without entering into the composition of any of the organs of the body. Is, then, the substance from which the sulphocyanide is derived (? taurocholate of soda) the product of the chemical changes connected with the conversion of the peptones into the circulating albumen, or is it the result of the decomposition of the vitalised material? If the latter were the, case we should find the amount of the salivary salt bear some relation to that of the urea in the urine, and I have not, unfortunately, a sufficient number of cases recorded in which the quantities of these two substances were simultaneously determined so as definitely to settle the question.

In non-febrile conditions I have generally found that an excess of the sulphocyanide corresponded with a high specific gravity of the urine, but this probably arises from the fact that the introduction of an undue amount of nutriment into the system is quickly followed by an increased metabolism, whereby the surplus nutriment is broken up and eliminated. But during the course of a febrile disorder the quantity of the salivary salt is not increased, as you will see in the case of typhoid fever, although the amount of urea eliminated is excessive, and it is not until the fall of the thermometer and the renewal of the functions of the stomach and liver that the quantity of the sulphocyanide is augmented. Pointing in the same direction is also the fact that, as was before observed, the quantity of the salivary salt in acute rheumatism is not in proportion to the average height of the fever, so that from the data we possess we have no reason to conclude that the material from which the sulphocyanide is derived results from the destructive processes of the system. In addition to this, let me remind you that in the cases of granular kidney admitted with uræmic convulsions there was no large amount of sulphocyanide, but it increased as the patients improved in health; showing there is no connexion between the retention of the albuminous materials in the state of retrograde metamorphosis and the quantity of the salivary salt. I think, then, as far as we can at present see, the facts we possess seem to point to the conclusion that the sulphocyanide is derived from some substance separated from the peptones absorbed into the system from the digestive canal, and produced during the process (of the exact nature of which we are ignorant) by which these are converted into material fitted for the purposes of nutrition. This substance we have before seen reason to suspect is the taurocholate of soda, which is secreted by the liver and forms one of the constituents of human bile.

But if the sulphocyanide is only the ultimate product of the action of a number of secreting structures, such as the liver, duodenum (? pancreas), and the salivary glands, are we justified in expecting that its quantity can be accepted as a measure of the activity of the first of these alone? There can be no doubt that, as in the case of dyspepsia accompanied by sulphuretted hydrogen, an abnormal action of any of these structures may alter the amount of the sulphocyanide; and it is from feeling the force of this objection that I have trusted to averages rather than to isolated observations. By so doing, the statements have lost much in force, but they are, I think, more trustworthy for the purposes we have in hand.

The saliva of a person in good health varies but slightly, as regards the quantity of the sulphocyanide, at different times of the day, or from day to day. If secretion is very active, the colour with the iron is a little less deep; if, on the contrary, there is much dryness of the mouth, it is necessarily somewhat deeper, from concentration. It has appeared to me to be increased in persons in the habit of using alcohol in any form, and especially in those who consume malt liquors. Whenever, therefore, the salivary salt has been in abnormal quantity, I have advised these to be given up; and in most instances where the amount was deficient I have recommended either wine or some other form of alcoholic stimulant. In cases of excess of the sulphocyanide, I usually lessen the quantity of the animal food, and forbid soups and all fatty materials; when the opposite condition of the saliva is present, I prescribe as liberal a diet as the patient is able to digest. I have been often greatly assisted in the choice of an appropriate diet by the examination of the salivary secretion.

As regards the action of drugs, lead is the only one that has appeared to me directly to check the secretion of the salivary salt, but I have seen a temporary decrease produced by citrate of caffeine; but as the administration of it had been followed by nausea and vomiting, it is doubtful whether the change in the saliva may not have been produced by the sickness. The quantity of the sulphocyanide is always lessened by a long course of aperients, especially by salines, calomel, and podophyllin; but a single purgation, however brisk, seems to have little effect in this way. The alkalies, iodides, and bromides, in like manner, reduce the salivary salt; but all tonics, such as iron, quinine, and the vegetable bitters, have the opposite effect, probably by increasing the appetite, and thus augmenting the supply of albuminous material. Cod-liver oil seems to be especially efficacious in increasing the quantity of the sulphocyanide, but it rarely agrees where this is in excess of it.

The most accurate method of ascertaining the amount of the salivary salt is to obtain all the saliva the person is able to secrete in five minutes, adding to it the tincture of perchloride of iron in the proportion of one drop to a drachm, filtering this through a little cotton wool, and then to compare the colour with solutions of sulphocyanide of iron carefully graduated. The bottles containing the tests and those to be compared with them should be of exactly equal size, and those used by spectroscopists are best fitted for the purpose. I found that 320 milligrs. of sulphocyanide of potash added to 300 cc. of water containing 24 cc. of the tincture of perchloride of iron produced a colour eight times the strength of that which I adopted as the normal. This plan has, however, the disadvantage of requiring the tests to be replaced every six or eight weeks, as in that time the colour begins to fade. A better method is therefore a great desideratum. For ordinary use in practice I have been in the habit of using my own saliva as a test, and guessing the amount of increase or decrease as compared with it. In bringing before you this interesting subject, I must remind you that the facts I have adduced and the attempts to explain them are on a very different footing. The facts you can easily verify or disprove—only, in doing so, be careful to use the necessary precautions to avoid errors, and do not too hastily condemn the results of many years' experience. I cannot expect to have solved all the difficulties of such an intricate subject, for, as in the case of the thermometer, varieties must occur from the temperament of each person and the circumstances by which he is surrounded. As regards using the facts for practical purposes, let me remind you that, although the nutrition of a patient is a most important matter, it is not the only thing to be attended to, for circumstances may force you for a time to put aside its consideration and direct your attention to other structures, the abnormal condition of which are threatening his existence.

As regards the explanations of the facts we have been considering, they seem to me to be the most probable I can offer you, but it would be absurd of me to say they are necessarily correct. Let me remind you that physiology has as yet not offered even a plausible conjecture as to the occurrence of the sulphocyanide in the saliva, the uses it

Digitized by Google

performs, or the materials from which it is derived. Nor is more known of the changes that the inflowing tide of nutriment undergoes before it is fitted to perform its part as a portion of the living animal, although we are sure a knowledge of this subject must be of the greatest interest both to the physiologist and to the investigator of disease. Physiology should ever precede and guide inquiries into all disordered functions, and it is only when it fails that pathology may venture to cast its more dubious light upon the darkened path. If I can be the means of attracting the attention of those better fitted than myself to elucidate the difficulties environing the whole of this intricate subject, I shall consider the labour I have expended upon these inquiries as amply repaid.

THE RECENT RESEARCHES IN CONNEXION WITH THE ETIOLOGY OF SCARLET FEVER.

By EDGAR M. CROOKSHANK, M.B.,
LECTURER ON BACTERIOLOGY, KING'S COLLEGE, LONDON.

THE last link in the chain of evidence in favour of believing that the Hendon cow disease caused human scarlatina was afforded by the researches of Dr. Klein—that is to say, when it was taken for granted that these researches could be accepted without question. Indeed, assuming this evidence to be correct, and attaching it to the cogent arguments brought forward by Mr. Power, such a strong case was made out that the subject appeared to be almost beyond the region of controversy. The researches of Drs. Jamieson and Edington, of Edinburgh, which have just been published, have thrown a cloud of doubt over the evidence adduced by Dr. Klein. The Edinburgh research carries with it the weight of considerable authority, and, though somewhat incomplete, appears so careful that it cannot be overlooked. On the contrary, an impartial criticism is called for of the evidence brought forward on both sides.

In the Eighteenth Annual Report of the Local Government Board (1885-86, pp. 90-99) Dr. Klein describes in detail the course followed in his investigation. The effect of direct inoculation with the matter of the ulcers of the diseased cows first claimed attention. No result was obtained by inoculating ten guinea-pigs. In one out of four dogs an ulcer resulted, which healed on the tenth day. In four cows the places of inoculation became swollen, tender, and spreading; the marginal part showing vesiculation, and the centre formation of a crust. In from nine days to a fortnight these ulcers healed.

From these experiments Dr. Klein concluded that this disease of the cow was directly communicable from animal to animal. The question then arose as to the existence of any specific micro-organisms. Cover-glass preparations were made from the matter expressed from an ulcer: cocci, diplococci, and streptococci were discovered which did "not differ from those described in connexion with foot-and-mouth disease." In sections the same diplococci and streptococci were found in the contents of the superficial cavities as well as the depth of the epithelium. From the deeper parts of an ulcer tubes of nutritive gelatine were inoculated. In these media a growth of streptococcus resulted, which was "very similar to that presented by the streptococcus of foot-and-mouth disease." In gelatine tubes the streptococcus of foot-and-mouth disease is a little faster in its growth, and the component granules are a little more distinct. Nevertheless, Dr. Klein adds that in some tubes of both kinds of organisms in gelatine and in agar-agar the general appearances could not be easily distinguished. Only by one test can the organisms be readily distinguished—namely, by the different result obtained by cultivation in milk. In form, mode of division, branchings of the chains, and in the presence here and there in the chain of a large element amongst the smaller ones, the organisms of the Hendon cow disease are admitted by Dr. Klein to hardly differ from the description he was preparing of the streptococcus of foot-and-mouth disease. These points are entered into in detail to first of all correct an idea, which is very prevalent, that the so-called streptococcus of scarlatina is an organism in its morphology and characters on cultivation, [illegible] *markedly* in these particulars from other organisms viously described. This idea has doubtless arisen interpreting the statement of Dr. Klein that the of scarlatina "in its mode of growth on nutriti on agar-agar mixture, on blood-serum in broth and proved very peculiar and different from other micrococcus hitherto examined."[1]

The next stage in the inquiry involved the st effect of inoculating these artificial cultivati calves were inoculated; one died and the other In neither of these cases was a "real ulcer" prod the post-mortem appearances recalled to Dr. Klein human scarlatina. In the blood from the heart calves a few diplococci and streptococci could b and cultivations were made from the blood in t taining nutritive agar-agar. A growth, it is st obtained of a streptococcus which was in all identical with the streptococcus that had been emp inoculation. We are not informed in what per the tubes the streptococcus grew, or whether organisms appeared in any of the tubes. How the statement that only diplococci and a few st were observed, we may fairly conclude that the re microscopical examination of the blood and of the o was to reveal the fact that *only* diplococci and st were to be found in the blood of an animal inocul the Hendon cow disease. No plate-cultivations have been made to ascertain whether the diplococ be grown apart from the streptococcus, or whet only a phase in the life-history of the streptoco Klein apparently takes this for granted, and conclu these experiments that the streptococcus is ident the virus of the cow disease. From the experim dence, we may conclude safely that this streptococc mately associated with the disease in cows, but that the same organism was responsible for the human scarlatina lacked at this time any exp corroboration. The inoculation of a known milk into the human subject was necessarily wanting there was obviously no distinct proof, so far, Hendon streptococcus could produce scarlatina in

Let us now examine the experiments which were to for supplying some further evidence in suppo theory just mentioned. An account of these ments will be found in the Proceedings of the Roya vol. xlii., March 3rd, 1887. Dr. Klein here recites sults obtained in the attempt to prove that human was dependent on the Hendon streptococcus; that, this streptococcus, when obtained from the human was capable of producing in the bovine species the ease as was observed in the Hendon cows and in experimented upon. The experiment consisted in cultivations in nutritive gelatine, nutritive agar-ag serum, and other media, from the blood of acute human scarlatina. Out of *eleven* acute cases, *four* positive results. In these four cases "several dro were used after the customary methods." Genera very small number of these tubes revealed, after tion of several days, one or two colonies of the strep

There is no record of any control tubes being i from the blood of persons in health and kept u same conditions of incubation. This may not appe essential, but if it had been done and no Hendon cocci had occurred in them, Dr. Klein would ha himself from the criticism that the scanty growth tubes inoculated from scarlatinal blood might po attributed to accidental contamination in the labora

There is, however, another possible explanation appearance of only a scanty growth in so small centage of the tubes—namely, that this strepto is only occasionally associated with scarlatina; that in fact, possibly be identical with the *streptococcus lorum*, which was isolated by Löffler from a diphtheria, and subsequently encountered by Heu Bahrdt in post-scarlatinal suppuration. This org inoculation in the lower animals was found to a rash, and to be very closely allied, if not identical, streptococcus which Fehleisen believed to be the erysipelas.

In further support of his conclusions, Dr.

[1] Proceedings of the Royal Society, March 3rd, 1887.

Digitized by Google

announced the discovery of the Hendon streptococcus in condensed milk which was suspected of having caused an outbreak of scarlatina. This organism appears on inoculation to have produced a similar disease to the disease of the Hendon cows. Again, in the tissues and blood of a monkey which died, it is said, from drinking suspected milk, the same streptococcus was found. But the conclusion that the animal died of scarlatina was merely speculative, and the omission of any experiments with scarlatinal blood or with the cultivated streptococcus, to prove that a healthy monkey could suffer from scarlatina with the reappearance of the streptococcus, is a very grave one. One must admit, then, that the experiments with scarlatinal blood are not sufficient and complete enough to justify the belief that the contagium of scarlet fever is a streptococcus which will produce in cows the Hendon disease. And yet this is the key to the conclusions that have been arrived at, and it will therefore only be when Dr. Klein's experiments have been extended and confirmed that we shall be justified in saying that the cow disease is distinctly proved to be a cause of human scarlatina. Without this we are only justified, from a purely bacteriological point of view, in concluding that Dr. Klein has isolated and cultivated a streptococcus which is intimately associated with a peculiar eruptive disease of the udders and teats of cattle. That the contagium of scarlet fever may be conveyed by milk is an accepted fact, but whether this disease in cows is a source of the contagium is another question altogether.

Let us now pass on to consider the Edinburgh researches which were alluded to. In the latter end of October, 1886, Dr. Edington received instructions from Professor Chiene to make investigations into the desquamation and blood in human scarlet fever. These investigations were carried out with every possible practical precaution, especially with respect to avoiding contamination of cultivations. Several different organisms were isolated and studied. Two of these appeared to be especially important—the provisionally named *diplococcus scarlatinæ sanguinis* and *bacillus scarlatinæ*. The diplococci occurred in 45 per cent. of the inoculations from the skin; the bacilli in 30 per cent. of the tubes inoculated from the blood, and in every case, with the exception of one tube accidentally broken, in the tubes made from the desquamation—i.e., if taken after the termination of the third week and never before this; the bacilli also occurred in every tube made from scarlatinal blood if taken before the third day of the fever. These bacilli measure from 1·2 μ to 1·4 μ in length, and ·4 μ in width. They readily grow in nutritive jelly, and rapidly liquefy it, but without producing any characterstic appearance. The bacilli are, according to Dr. Edington, to be seen in cover-glass preparations of scarlatinal blood. Inoculation of the bacilli produced in rabbits erythema and fine desquamation, in guinea-pigs erythema and coarser desquamation, and in calves febrile symptoms and a rash followed by desquamation. Further, blood direct from a case of scarlatina injected into a guinea-pig produced also erythema and desquamation. It was an unfortunate omission that the direct inoculation of blood was not also made in a calf, as we should have been able to compare the results with the Hendon disease.

As another omission in this research I may mention the absence of any control experiments with the bacteria found on the skin in health. It may be urged that these have already been studied by Biszozero and by Bordoni Uffreduzzi. The latter found several cocci, a bacillus, and a saprogenic bacterium. The *bacillus epidermidis* measures 2·6 μ to 3 μ in length and ·3 μ in width. It grows but scantily in nutritive gelatine, and pure cultivations inoculated into rabbits and guinea-pigs produced no effect. This bacillus obviously differs very markedly from the *bacillus scarlatinæ*, but nevertheless it would have been much more satisfactory if these experiments had been repeated with a view especially to ascertaining whether there might not be another bacillus, though not met with by the Italian investigators, which would prove on cultivation and inoculation to be identical with the bacillus credited with being the contagium of scarlet fever.

Thus we have brought face to face independent observations on the contagium of scarlet fever, with the perplexing result that neither of the observers finds the special organism described by the other as the specific one. Dr. Klein found and cultivated his streptococcus by the "ordinary methods." A lack of knowledge of these ordinary methods can hardly be supposed on the part of Dr. Edington, which might account for his overlooking the streptococcus. On the other hand, it is evident that Dr. Klein never encountered in his researches the Edinburgh bacillus.

We must bear in mind, in connexion with this subject, that saprophytic organisms may occur in man, both in health and in disease, which produce very characteristic symptoms in the lower animals.

If they gain access to the circulation through some surface lesion, they may, in an advanced state of disease especially, escape disintegration and be detected in the blood and in the organs after death. Thus they may readily be mistaken for the specific organism, if there be one, of the disease in question. We may also find more than one organism associated with a disease as the result of a double infection. Kassowitz and Hochsinger found in the organs of children who had died of congenital syphilis streptococci, which were regarded as the result of *Mischinfection*. It is interesting also to recollect how commonly streptococci have been met with. In addition to those I have already mentioned, we must bear in mind the streptococci in purulent inflammations found by Ogston, Rosenbach, Krause, Garrè, Hoffa, and Biondi, the streptococci found by Weichselbaum in acute pneumonia, the streptococcus isolated by Nicolaier from earth, the streptococci found by Emmerich in the air, and, I may add, the streptococci found by Babes in the liver and kidney in two cases of yellow fever; in the liver, kidney, and spleen in a case of *fièvre typhoïde bilieuse*, and in inflammatory products consecutive to scarlatina, by Bokai and by Babes in joint affections after scarlatina, and by Charrin in septicæmia consecutive to anthrax in rabbits. In conclusion, it is obvious that the experiments which have been analysed must be repeated and extended before a definite opinion can be expressed; and as in addition to its pathological interest the inquiry involves a question of national importance, it is to hoped that a commission will be appointed. By testing the result of inoculating blood from human scarlatina direct into the calf and the monkey, and by repeating and extending the experiments of Dr. Klein and Dr. Edington, there ought to be no difficulty in dispelling the present contradictions.

ON LATERAL CURVATURE OF THE SPINE.

By RICHARD BARWELL, F.R.C.S.,
SENIOR SURGEON, CHARING-CROSS HOSPITAL.

LATERAL curvature of the spine is, it appears to me, a subject of increasing importance; because, if I am to judge by my own considerable practice in this branch of surgery, the victims of that condition are yearly increasing in numbers. The fact is in part to be ascribed to the greater pressure of school work, more and more carried on in writing, to which young girls are now subjected. Before, however, discussing the etiology and treatment of spinal curvature, it will be necessary to give some few explanations and definitions.

Lateral curves receive from the direction of their convexity the name of right or left, and they are termed dorsal or lumbar according to the region they affect. Most curvatures are double or S-shaped; but in some cases the upper, in others the lower, bend is the original evil, and is named primary dorsal or primary lumbar; the other curve, called secondary or consecutive, is an addition forced upon primary curvature probably by the necessities of balance. Other varieties, however, are not uncommon. Thus the whole spine may be bent either to the right or left in one long curve from top to bottom; and we occasionally meet with multiple curvatures—i.e., cases in which the spine is bent in a series of three or more sharp short curves, alternately to right and left. Combined with the bend of the spine is always rotation of vertebræ,[1] in such sense that the anterior faces of the vertebræ always look towards the convexity, and the tips of the spinous processes towards the concavity of the curve. This connotes that the transverse processes of the lumbar, those processes and also the ribs in the thoracic region, project abnormally backward on the convex side, and are too little prominent

[1] The contention of Nicoladoni and Hüter, that rotation as seen clinically and in the skeleton is merely an ocular delusion, is quite untenable.

Digitized by Google

on the concave side of the curve; also that the muscles—more especially do I here refer to the erectors—no longer act symmetrically on each side of the mesian line, but unilaterally and in a false direction. But although it is true that in all cases of scoliosis the vertebra which has deviated most from the straight line is also that which has most rotated, curvature and rotation do not in different cases bear the same proportion to each other; but, on the contrary, the one or the other may be the predominant deformity in any given instance.

Theories as to the causes of these deviations are very numerous—more so, indeed, than can be here specified. Rather more than twenty years ago, when the first edition of my work on lateral curvature was published, I named most of them, and pointed out where they failed to account for the phenomena; also I showed that all these curves, and perhaps some examples of rickety scoliosis, are produced by one-sided muscular action. This view has, of course, met with a certain amount of adverse criticism, chiefly from those who assert that lateral curvature is due to certain postures. Such contention, as opposed to the theory of asymmetrical muscular action, is, however, a mere *logomachia*, for it must be evident that postures, except those assumed in recumbency, are the results of muscular

FIG. 1.

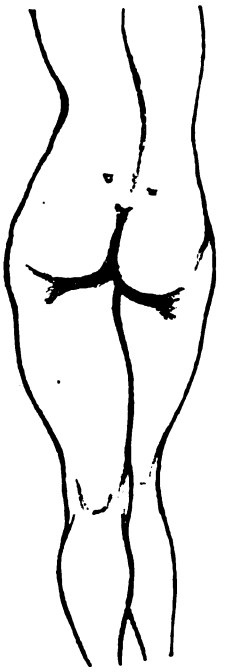

FIG. 2.

acts. Therefore, even after studying and giving full attention to the various objections that have been made, I again assert the correctness of my theory, including in the term—predominant action of muscles on one side of the body—any and every peculiar posture which such habitual predominance may maintain. Thus, in a young subject any one-sided predominance, be it respiratory, be it postural (either from mere habit or occupation), or be it from difference in the length of the lower limbs, may, and often does, produce a lateral curve and twist of the spine, which at first is an affection of soft parts only, but which after a time produces certain deformations of the bones. The exigencies of small available space will not allow me to go thoroughly into the many changes which are thus produced in the vertebræ; but, to place the matter as shortly as possible, I will ask the reader to picture to himself a rapidly growing girl between the ages of seven and fifteen, who has from one of the above causes acquired a constant, or nearly constant, side twist of the spine. It is evident, firstly, that the ligaments on the convex side will become lengthened, those on the concave side shortened, binding the vertebræ still more fixedly in their false position. Moreover, since the bones are still growing, more especially from the junction-lines of the epiphysial plates and from the neuro-central suture, it happens that the growth of that side upon which more weight is thrown will be diminished, of that upon which less weight is thrown increased; therefore the vertebral bodies become after a time wedge-shaped—thicker, that is to say, on the convex, thinner on the concave side of the curve; the pedicles also, and to a less extent the laminæ on the concave side, are shortened and generally stunted; in bad cases they are changed in direction, as are also the articular processes and their facets. Later on both the transverse and the spinous processes also are deflected and misplaced. The condition is now very different from that first described: the habitual curve has become what is termed permanent. I need hardly point out how much more grave is this latter condition, nor how important it therefore is to correct the earlier phase, while still merely habitual.

One of the most common forms of curvature whose etiology is the most simple is lumbar curvature, and this perhaps rather more commonly to the left; it originates in the vast majority of instances from pelvic obliquity—i.e., from one side of the pelvis lying on a lower level than the other, which means of course that the sacrum also slopes, and that the basis on which the spinal column stands is awry. Therefore the column itself, in order to preserve its and the body's balance, must be deflected or, in other words, the spine must curve. Pelvic obliquity may result from unevenness in length of the two lower limbs—a condition constantly arising from disease or injury, but very often found when no such causation can be traced. Such unprovoked inequality is much more common in girls than in boys, and usually, though by no means always, the right limb is the longer one. Fig. 1 is from a lad whose left limb is short, probably from early and transient infantile paralysis. An extreme case has been chosen in order to show more clearly the oblique position of the pelvis and the curve of the loins therefrom resulting. While Fig. 2 (which will be reverted to again in the subject of treatment) shows how a block under the foot compensating the shortness of the left limb will restore the horizontal position of the pelvis; and since this device straightens the spine, it also shows how long even an extreme habitual curve may by judicious management be kept in that phase. But pelvic obliquity is not always the result of uneven limb growth. It sometimes is produced by a mere trick or habit, such as many young girls acquire, of standing on one leg and letting the other fall loose with bent knee; and unfortunately the habit is to thus use always the same limb; the result is the same as though one were shorter than the other—viz., pelvic obliquity, as shown in Fig. 3.

FIG. 3.

Another condition has, I am convinced, considerable influence on the production of curvatures, especially as it occurs at a period of life when growth is rapid, when muscular development is in progress, and while yet the spinal epiphysial junctions are soft and active. This condition is due to the increased and increasing study now forced on girls chiefly through the medium of writing, and is in all probability the chief cause of a greater prevalence of lumbar curve to the left, which, as stated in my opening sentence, I have observed during the last ten years. Writing, of course, has no evil influence on the spine provided the pupil sit square and even on the chair and before the table, but very many sit so as to support the weight on the right ischium and right arm, the spine being bent (convexity to left) chiefly between the last lumbar and tenth dorsal vertebræ. Some girls even exaggerate this evil posture by pushing the chair back from the table and bending the body still more over.

Doubtless certain other more recondite causes of lumbar curve exist, such as constantly crossing, during sitting, the left leg over the right; also certain uterine and ovarian

Digitized by Google

conditions causing uneasiness, for which relief is sought in some faulty posture of standing, sitting, lying, or all three. These are, however, exceptional, and rarely produce other than slight curves. In all curvatures primarily lumbar rotation plays a less prominent part than in dorsal curves. In certain cases it is very slight, in others more marked in proportion to the deviation, but is never so considerable or so important as it is in most cases of dorsal curvature. In another paper I shall describe the diagnosis and treatment of loin curvature.

Wimpole-street, W.

ON SOME

RESULTS OF CICATRISING PROCESSES IN THE NEIGHBOURHOOD OF THE PORTAL FISSURE.

BY HENRY F. A. GOODRIDGE, M.D., F.R.C.P.,
SENIOR PHYSICIAN TO THE ROYAL UNITED HOSPITAL, BATH.

(*Concluded from p. 1227.*)

THE second case exhibits cicatrisation bringing about in the same way a different result; as will be observed, it has an additional connecting link with the first case.

J. T——, aged eighty, was admitted on May 25th, 1875. She stated that through the whole of her life up to the last winter but one she never had any illness; she then had what she called "the cold shivers" with slight cough. Her present attack commenced between four and five weeks previously with pain over the region of the liver, shooting through to the right shoulder blade; at the same time she became jaundiced. Her bowels were confined, the stools being light-coloured; and her urine was very dark. She had vomited three or four times during the last week, and her appetite had failed. On admission, she exhibited marked jaundice, but the pain had pretty well subsided. Her temperature in the axilla was 97°; pulse 68, radial artery senile; respiration 32; and tongue moist, but coated with whitish fur. Her bowels had not been open since the 23rd, when the stool, it was said, was pale; the urine was acid, sp. gr. 1017, very dark, and on testing showed the presence of bile pigment. She had some itching of her skin.

May 26th: She had slept well. The bowels had acted slightly, the stool being clayey. Her temperature was 97·4°, pulse 64, and respiration 28. The liver extended to near the umbilicus; it did not feel hard, and presented no inequalities of surface except at the extreme right, where there seemed to be a small hard nodule on the convex surface; it was near the edge, which could be distinctly felt all along, but was not thickened or rounded. There was apparent distension of the ascending colon, a feeling as of a firm tube extending vertically under the right rectus muscle.—28th: She had had good nights, and her appetite was improved. When she had taken a little wine that was ordered she said it gave her pain in the stomach. She vomited once in the evening.—June 1st: She had had no further sickness, and had no pain whatever. She was sleeping well and taking her food well. Her temperature was 97°, pulse 56, and respiration 24. A little brandy-and-water, which was substituted for the wine, she said she could not get on with.—15th: She had had some bronchial catarrh the last few days. Her bowels were open about once daily; the stools had continued clayey, but were now of a slate colour. She passed upwards of thirty ounces of urine in the twenty-four hours. The jaundice was much as before.—20th: She had vomited several times to-day.—25th: There had been no return of vomiting. Her cough had continued troublesome. She had no pain. Her temperature was 96°, pulse 72, and respiration 32. Her bowels were open daily, the stools being still slate-coloured. The jaundice was much as before.—26th: About 3 A.M. she began to vomit black coffee-ground-like matter. At 9 this had amounted to upwards of two pints. She had no pain, but felt exhausted; her pulse was 116 and very feeble. There was a little tenderness on pressure in the epigastric region, none elsewhere. In the vomited matters were numberless red blood-discs. The patient became much collapsed and died the same evening.

Necropsy, forty-four hours after death.—On opening the abdomen the liver presented nothing remarkable, except near the margin of the right half of the right lobe, in the situation where was observed the hard nodular feel during life. Here the convex surface exhibited an opaque yellowish white puckered look; in fact, the appearance of a large cicatrix with some amount of central depression. The texture was dense and indurated, and this condition was felt to extend through the entire thickness of this part of the organ. Underneath was a thick, tough, and pretty extensive adhesion of the transverse colon, so that only by the knife could the intestine be separated. Its lumen was slightly diminished in consequence, and on opening it there was found some puckering of the mucous surface, but no ulceration. On making a section through the indurated portion of the liver here, the same cicatricial character was observable. Corresponding somewhat in situation to the gall-bladder was a small cyst-like cavity that would contain about one fluid drachm; a little mucoid matter was in it; there was no trace of duct. The opaque tissue gradually and in a somewhat radiating manner passed into the surrounding hepatic texture. The capsule could not be separated over this part. There were also some diaphragmatic adhesions and thickening of the capsule, but nowhere else in the organ was there any appearance similar to that described. The hepatic duct, as it issued from the liver, was quite pervious; so also was the common bile duct at its entrance into the duodenum, but even a No. 1 catheter would not pass through the latter. The liver weighed 40 oz.; its parenchyma generally was coarse. No gall-stone was found anywhere. The stomach was considerably dilated. It contained a quantity of thin melanic fluid like what had been vomited during life. Near the small curvature on the posterior wall, but not so near the pylorus, was a largish ulcer, which reached to the peritoneal coat, and was distinctly terraced. Just within its margin, which presented no thickening, was the open mouth of an artery, evidently a branch of the coronary. The kidneys were somewhat granular; the two together weighed 6 oz. Nothing important was found elsewhere.

Now, the cicatricial appearances in this woman's liver had *primâ facie* very much the characters of a syphilitic lesion; I was disposed, however, to think that they were due to an old suppurative inflammation of the gall-bladder, perhaps connected with gall-stones, which had discharged by a fistulous opening into the transverse colon. Be that as it may, the origin of the cicatricial tissue does not so much concern us as its presence, and its presence in quantity, in the substance and on the under surface of this part of the organ; though here, as in the case of A. M——, the products of adhesive local peritonitis were clearly more or less blended with it. Caught apparently in one part of its course within the fibrous bands of this contracting tissue, the common bile duct became constricted, and jaundice ensued. As to the ulcer in the stomach, we may remark in passing that possibly it owed its origin to arterial degeneration, which is recognised by authorities as a cause of gastric ulcer in old people. The same condition might also explain how it was that the hæmatemesis was not of that florid and instantaneously fatal character that the size of the gaping artery would have led one to expect.

The products of adhesive inflammation have been above referred to as having had a share in bringing about the pathological events under consideration. These products and cicatricial tissue, we know, are histologically closely allied forms of fibrous connective tissue, and they possess alike the property of contraction. In the cases before us the share taken by the inflammatory products was a subordinate one; but in some instances, as, from the facts just noticed, and from our acquaintance with the operation of such products on a larger scale elsewhere, we might well anticipate, they show themselves capable *per se* of inducing similar results. "Now and then the fibroid tissue developed in the portal fissure from the products of inflammation produces constriction of the bile duct or portal vein."[1]

It is not unimportant, I think, to discriminate between cases such as we have been considering and those where vessels, ducts, &c., are compressed by the gradual stuffing by adventitious products of the spaces wherein they run. Thus, in a case of lymphadenoma of the retroperitoneal glands under my care, "the disease had attacked also the portal glands, and a considerable mass was found deep between the liver and stomach, in which the vessels in the portal fissure were embedded. On cutting transversely

[1] Murchison on Diseases of the Liver, 3rd edition, p. 310

Digitized by Google

through the mass, the common bile duct, the hepatic artery, and the portal vein were divided, their mouths being quite patulous and their calibre undiminished."[2] The tissue here possessing no marked contractile property, the vessels, though embedded in the same, did not suffer. At a further stage of the growth, of course, compression would ensue, with narrowing or occlusion of one or more vessels, according to the resistance they might respectively offer. But then the *modus operandi* would be that of a pretty uniform constriction, comparable to the slow tightening of a ligature. Not so, however, in the class of case dealt with in this paper. We use the terms *contraction* and *constriction* in discussing the same, but, as has been pointed out, the contraction of cicatricial tissue in cases of this kind is, strictly speaking, a *concentric retraction*, a shrinking which takes place in all dimensions, and is directed in radial lines towards a centre or centres which are determined by the conditions of the original lesion, and the foci, one or more as the case may be, of tissue destruction. Hence the effect on vessels, ducts, &c., traversing the area of cicatrisation, is rather an irregular traction or torsion than a uniform constriction as in the former instance. And hence also it happens, that in the same cicatricial area, while one vessel is implicated, another is not at all so, or only in a minor degree.

Bath.

THE RELIEF OF THE MORPHIA CRAVING BY SPARTEINE AND NITRO-GLYCERINE.[3]

BY OSCAR JENNINGS, M.D., M.R.C.S.,
ELECTRICAL PHYSICIAN TO THE CLINIQUE OF ST. ANNE.

IN a note on the Condition of the Pulse in Morphinomania presented by Professor Ball and myself at the French Academy of Sciences,[4] we discussed the mechanism of the morphia craving, and showed that during the period of privation there is ischæmia of the general circulation. An injection of morphia administered at this time causes a disappearance of the psycho-somatic suffering which constitutes the craving, and is followed by a restoration of the pulse. In a second communication to the Academy of Medicine[5] we stated that we had found, moreover, that the morphia craving can be appeased by the use of other medicines having the property of restoring the pulse in a similar manner. We had experimented extensively with two agents of the kind on patients at Laennec, St. Anne, and in our private practice. The first of these is sparteine. "We thought it would be preferable to try heart tonics, and strengthen the action of this organ in moments of weakness. To this end we have employed sulphate of sparteine, which fulfils most of the conditions, and can easily be administered by hypodermic injections. We watch for the moment of weakness as indicated both by *plateau* in the sphygmographic tracings and by the intimate sensations of the patient. At this moment we administer an injection of from two to four centigrammes, which may be repeated when necessary, and at the expiration of a few minutes we see the pulse strengthen and the craving disappear. To use the words of one of our patients, 'the medicine gives heart.' This expresses in familiar language a physiological truth of which the sphygmograph confirms the absolute exactitude..... Another medicine which procures a passing relief of the symptoms is nitro-glycerine. Its effects, very similar to those of sparteine as regards the point in question, are at the same time much more rapid and much more ephemeral."

Since the preceding lines were written I have administered sparteine and nitro-glycerine repeatedly in fourteen different cases, and I feel convinced that in these agents, properly administered, we possess a means which will enable any morphia *habitué* earnestly desirous of leaving off his intemperance to carry the process of weaning to a successful issue. All morphia *habitués* have from time to time a maudling hysterical desire to give up the practice, but this vanishes at the first feeling of discomfort. For such cases there can be no suppression without restraint, and a result so obtained is very unsafe for the future. Deprived of their morphia in an asylum, patients are not thereby cured of the craving. They have been forced by a compulsion, which has provisionally taken the place of their will, and a morphinomaniac is no more cured of his passion by this forced deprivation than is the dipsomaniac by abstinence from alcohol during a certain time. A relapse generally occurs as soon as the patient has recovered his liberty. But there are morphia *habitués* who honestly loathe their thraldom, and who would do anything short of the impossible to break through it. Very few medical men seem to realise the nature and intensity of the suffering which accompanies the privation from morphia, and upon which they are occasionally called upon to advise. A gentleman, whose case I related in the *Encéphale of* March, 1887, and who was cured of the habit by inhibition of the craving, was informed by some of the consultants he had seen that the confirmed habit of morphia was incurable. I believe it is the writer of the section on Morphinism in Ziemssen's Cyclopædia who is responsible for this opinion. But the greater number of his previous advisers had been of opinion that all that was necessary to cure him of the habit was for him to "throw away his syringe and solution, and just make up his mind not to get any more."

Now, the truth lies between these extremes of theoretical error and practical ignorance. Some morphia *habitués* would have sufficient resolution to wean themselves of the practice of the terrible distress resulting from privation if this could be alleviated in a certain measure; and it is to these that I refer when I say that those who are earnestly desirous of breaking off the habit can be enabled to do so by the help of sparteine and nitro-glycerine. To be properly administered the remedies mentioned must only be used when really needed, and should not therefore be at the patient's disposal. The only results I have ever seen of giving succedanea to morphinomaniacs has been to complicate the first disease by a second, and very often a much more dangerous, intemperance. And just as I have seen morphia *habitués* acquire an additional craving for alcohol, chloral, cocaine, and other drugs of the kind, so I think it quite possible that the reckless and uncontrolled administration of the medicines I recommend may give rise to an artificial desire for them—a possibility foreshadowed by Dr. Murrell in his work on Nitro-Glycerine in Angina Pectoris. Given at the right moment, and in suitable doses, sparteine and nitro-glycerine, either separately or together, form an admirable means of relieving the morphia craving, and the only modification I have to make in the statement quoted above is with reference to the intensity and duration of the action of nitro-glycerine. Further, experience has taught me that the effect of nitro-glycerine is most satisfactory and persistent in those cases where there is a predominance of the "yearning" over the "craving"—that is to say, in which the psychical symptoms are more distressing than those of a somatic order. When, on the other hand, there is more physical craving than morphine-nostalgia, as I have termed it, the use of sparteine, which is a tonic to the circulation, gives better results than nitro-glycerine alone, which I take to be nervo-inhibitory. What, however, I would especially insist upon in the present note, is that, in the simultaneous administration of the two drugs, the one by subcutaneous injection and the other placed upon the tongue, we possess a perfect remedy for the morphia craving in its double psycho-somatic modality. Some patients, as would naturally be expected, say that one or both drugs fail to give them relief; but, as far as my experience goes, these are persons who have no real intention of giving up their morphia. Indeed, all they desire is to be allowed to indulge without interference in their vice. But those who have retained sufficient will to resist the first promptings of a capricious impulse will find that the true morphia hunger can be entirely appeased by sparteine and nitro-glycerine taken when there is a genuine necessity. The subjoined sphygmographic tracings show better than a lengthened description the relative values of the two remedies.

Tracings Nos. 1 and 2 were taken from a patient at Laennec, whose case is partially reported in my little work on Morphinomania,[6] No 1 being before, and No. 2 after, an injection of morphine; the first shows the state of suffering, the second that of satisfaction. No. 3 is a tracing of the same pulse after a hypodermic injection of sparteine instead of morphine. The patient having stated that the sparteine

"gave her heart," the morphia was suppressed, and she was given two grains per day of sparteine instead of half a grain of morphia, to which she had decreased from eight grains, to which she had been accustomed for seven years. Thanks to the sparteine and occasional faradisation, she got over the craving in three weeks.

Nos. 4, 5, and 6 are the sphygmograms corresponding to different degrees of morphia hunger in a young medical man, who had taken morphia for insomnia six years previously, and had become accustomed to twelve grains per day. The whole suppression took less than a month, and fifteen days after the last injection of morphia his pulse kept up by nitro-glycerine was as in No. 7. A few days later he was entirely cured, and took no substitute whatever. In a letter to me on the effect of the different medicines employed, he says: "Antipyrin congested the brain the first time. At the third or fourth trial it produced no further effect. Its action diminished progressively. As to any relief it procured, it was very trifling. What did procure me the greatest relief, and which replaced by its effects the morphia, was without doubt nitro-glycerine. In a state of craving, at the time of my worst sufferings two or three drops, taken every three or four hours sufficed to remove all agitation and restlessness, and perhaps also perspiration. I will not be positive about this last point, as I only remarked it once. As regards the nitro-glycerine, its action increased progressively. I tried the tablets of nitro-glycerine, which had the same effect as the solution, and at the present moment it suffices for me to take a single tablet to congest the brain, and so procure a mild and pleasant intoxication resembling that of morphia."

The next three tracings relate to a woman whose pulse during her cure at St. Anne presented the truncated appearance which constitutes the *plateau* of morphia craving. The administration of sparteine had enabled her to be weaned of morphia without difficulty. Six weeks after the cessation of the treatment I took her pulse with a view to ascertain whether her habit, which was of ten years' duration, had left any permanent injury to the vascular tonicity. The tracing No. 8 indicated that the circulation was unsatisfactory, and with very little persuasion the patient told me that she felt uncomfortable about the heart, and would certainly be obliged to resort to morphia when she recovered her liberty unless she could brace herself up by sparteine. I suggested that she should try nitro-glycerine instead, and placed successively four drops of the 1 per cent. solution on her tongue. Five minutes afterwards she said she felt much more comfortable, and the pulse showed an improvement as in No. 9. She still maintained, however, that something more was needed to keep her away from morphia, so I injected two centigrammes of sparteine, with the effect seen in tracing No. 10, the patient expressing herself perfectly satisfied.

The last three sphygmograms form an interesting contrast to the three preceding. The pulse tracing on the day before having been found by the clinical clerk to present my *plateau*, Professor Ball had ordered sparteine. The pulse at 10.30 was as in No. 11; but notwithstanding the satisfactory condition of the circulation, the patient was in a state of restlessness and enervation, unable to keep still, and crying hysterically. I gave her two drops of nitro-glycerine solution. The effect upon the circulation was greater than in any case I have seen; but although the hyperdicrotism made me feel a little uneasy, the patient was thoroughly comfortable and became quite cheerful. I remained with her an hour and a half, during which time she was calm and tranquil, and before leaving took a tracing, which showed that the arterial tension was entirely restored. (See No. 13.)

The last two cases are extremely instructive. The patient whose symptoms were associated with a condition of the circulation shown in Fig. 8 has a bodily malaise depending partly on an embarrassed action of the heart. Her urine contains albumen. Here the nitro-glycerine was insufficient, and it was not until the condition of the heart was modified by sparteine to that shown in Fig. 10 that she expressed herself relieved. The woman whose pulse is recorded in Fig. 11, on the other hand, was not, as far as physical investigation could discover, suffering from the effects of ischæmia, and yet her distress was painful to witness. Here the successful remedy was nitro-glycerine.

To sum up, the morphia craving is a complex suffering, at the same time cerebral and peripheral, each factor of which can be relieved by appropriate treatment. The organic distress may be soothed by sparteine, which recovers the heart in the same way as a hypodermic injection of morphia. The cerebral craving (or yearning), often the more painful of the two, corresponds to a want of habitual congestion. This can be arrested by nitro-glycerine, which gives rise to the same kind of sensation in the morphia *habitué* deprived of his stimulant as the hypodermic injection. It acts probably by inhibition *à distance* rather than by essential sedation of the nervous centres.

Paris.

CORKAGE OF THE URETER WITH CLOT IN CASES OF ADVANCED CANCER OF THE KIDNEY.[1]

BY E. HURRY FENWICK, F.R.C.S.,

ASSISTANT-SURGEON TO THE LONDON HOSPITAL, SURGEON AND PATHOLOGIST TO ST. PETER'S HOSPITAL FOR URINARY DISEASE.

I HAVE long been strongly impressed with the necessity for adopting some measure, other than excision, in the treatment of cancer of the kidney. The statistics of nephrectomy show the futility of removing a kidney thoroughly attacked by carcinoma. Cases such as these are often met with in practice, but sometimes there is superadded a profuse and ungovernable hæmaturia—a hæmaturia which prostrates our patient, defies our remedies, and which slowly, always surely, reduces that short term of life allowed by the disease to a minimum. In casting about for some conservative measure to arrest the hæmorrhage, without attempting to remove its source, I bethought me of the skilful manner in which the ureter is sometimes spontaneously plugged with clot, obstructed by growth, or pressed upon and rendered impassable by the enlarged lower segment of the kidney; the hæmorrhage being thereby suddenly and permanently arrested. Post-mortem examination of these cases shows the pelvis to be distended with a large firm blood clot, and the canal to be impervious. It seemed to me to be within the range of possibility to imitate this, by inducing clottage of the blood in the ureteral canal, and it did not seem beyond the range of probability that the mere pressure of the distended pelvis upon the renal vessels would restrain slightly the flow of nourishment to the neoplastic growth, and thus reduce its rate of increase. The course I proposed to myself to adopt in a suitable case was to introduce into the bladder some form of instrument which would allow of the vesical orifice of the ureter being nipped between it and the compressing finger in the rectum. The instrument I decided upon was my ureter aspirator,[2] which can be made to embrace either ureteral orifice without trouble. Although a good many cases of hæmaturia pass through my hands every year, yet it was not until 1885 that a case came under my care at St. Peter's Hospital which seemed to justify such an attempt being made. I submit this case not for criticism, for I regret to say it is incomplete; although its clinical aspect is strongly in favour of the conclusions I have drawn being correct, yet its pathological history is wanting, and without post-mortem evidence its accuracy is questionable and its value greatly diminished.

J. L——, aged fifty-three, had been healthy up to July, 1884. On the 31st of that month he received a severe blow upon his chest which caused him an hour afterwards to pass much blood in his urine. From that time he continued passing blood in large quantities and at irregular intervals for thirteen months. The hæmaturia was often apparently causeless in its origin, always painless in its course, and generally beyond the control of drugs. It used to stop gradually, only to reappear suddenly in a few days' time. Thirteen months after its onset he applied for relief at the out-patient department of St. Peter's Hospital, bringing with him a bottle of scarlet hæmaturia. He was at this time suffering from some pain in the right kidney, and had lately lost flesh and strength. He was very anæmic. There was no renal tumour to be felt, although pain was experienced on pressure in the region of the right kidney. No vesical or prostatic cause for the hæmorrhage was found. I explained the case to him, and, finding the hæmaturia unaffected by drugs, I advised attempting to close the right ureter with a clot, and failing

Digitized by Google

this to excise the kidney. He consented to the former operation. After carefully washing out the bladder I injected two drachms of a 20 per cent. solution of cocaine. I then introduced my right-sided ureter aspirating catheter, and turned it a quarter of a revolution on its long axis, so that the lateral eye of the instrument overlay the orifice of the right ureter. I now made a little counter-pressure per rectum with my left index finger, and exhausted the air in the catheter by means of its evacuator ball. On removing the catheter ten minutes after I found a large white clot, which I believed had been sucked from the ureter into the eye and shaft of the instrument, and I concluded that more of the same clot was collected in the lower third of the ureteral canal. Had I plugged the canal? With the exception of a little bleeding that night, which I believed came from the bladder instrumentation, *he had no recurrence of the hæmorrhage up to the date of his death six months after;* and this although the hæmorrhage for the previous fourteen months had been recurrent and profuse. The patient now rapidly picked up in health, weight, and strength. In three months' time, however, he relapsed, and I found, what I had often examined him for—viz., a right-sided renal tumour. The pain in the same region became worse, and in a month or two he wasted considerably, and finally died exhausted six months after my interference.

I had the opportunity of examining the patient shortly after the operation with Dr. B. Ward Richardson, and although there was no disagreement as to the site of the hæmorrhage, our opinion as to the nature of the lesion differed. This we expected to reconcile by post-mortem examination, a privilege which was, however, most unfortunately denied us. The case, therefore, must stand upon its clinical merits, but sinks in value in comparison with the question of the advisability and possibility of closing the ureter in cases of which the foregoing is an example. If it be possible, is it surgical? The answer to that question is ready but not complete. The interference is *imitative*, and is based upon pathological ground. It has the advantage of being painless, and though palliative it is strictly conservative. Its probable objection rests in the formation of a renal blood tumour, for there is but little renal substance left to form a hydronephrosis. Usually the hæmorrhage is directly into the pelvis, and the fibrous wall of the pelvis is rarely attacked, so that its integrity will generally prohibit the formation of a large blood collection.

Old Burlington-street, W.

TWO CASES OF

ACUTE COMPLETE INVERSION OF THE UTERUS AFTER DELIVERY.

BY MONTAGU HANDFIELD-JONES, M.D. LOND.,
OBSTETRIC PHYSICIAN IN CHARGE OF OUT-PATIENTS TO ST. MARY'S HOSPITAL, AND LECTURER ON MIDWIFERY AND DISEASES OF WOMEN AT ST. MARY'S MEDICAL SCHOOL.

CASES of acute complete inversion of the uterus are fortunately rare, and recovery after this accident is by no means constant: the notes, therefore, of the following cases may prove interesting, especially as they illustrate two varieties in the causation of this obstetric complication. The report of the second case has been kindly forwarded to me by my friend Mr. Ambrose Fairles, in whose practice it occurred.

CASE 1.—Mrs. I——, aged twenty-four, has been married three years, and has passed through two normal confinements. Naturally delicate, her health lately has been much depreciated by trouble and scanty feeding. In the present instance labour was attended with severe vomiting and diarrhœa and great exhaustion, but the birth of the child took place without further complication. The midwife states that, as after ligature of the cord and the removal of the infant the placenta was found to be lying in the vagina, she removed it at once, using for this purpose two fingers in the passage and gentle traction on the funis. "A few minutes" after removal of the placenta the patient complained of feeling unwell, and then fainted; free hæmorrhage occurred at the same time. Both the midwife and the mother of the patient were positive that no force was used in extracting the placenta, also that the sudden onset of alarming symptoms took place some minutes after the removal of the secundines. On arriving an hour later, the patient was found in a state of intense collapse (though brandy with ergot had been freely administered), and the uterus was completely inverted. In restoring the organ, no difficulty was encountered while replacing the lower segment; this unrolled easily and resumed its normal position, but the fundus gave great trouble: as fast as one portion was pushed up into position with the finger tips and then left in order to deal with another section, so certainly did the part last replaced reinvert. At length, under persistent pressure with the whole of the upper part of the right hand, the fundus reinverted with *a distinct snap*, and the uterus at once retracted, expelling the hand. Relief was immediate, and the symptoms of collapse disappeared with striking rapidity. The patient was up on the tenth day, and has lately passed through another confinement without mishap.

CASE 2.—Mrs. E——, aged thirty-four, the wife of an agricultural labourer, has passed through four confinements without any mishap. In the present labour everything went smoothly at first: the vertex presented, the pains were strong, and labour was rapid. As soon as the head had cleared the perinæum, the body of the child followed without delay, and then immediately the placenta appeared at the vulva, still adherent to the fundus uteri. The cord measured fifteen inches in length, and was unusually thick and strong. The shock to the patient was intense, as evidenced by the collapse, fainting, and death-like pallor. Recognising the nature of the complication, Mr. Fairles at once tied and divided the cord, and then, having quickly peeled off the placenta (a proceeding attended with much hæmorrhage), prepared to return the inverted uterus. Having grasped the mass of the fundus with the hand, no difficulty was experienced in pushing it upwards; but when the process was a little more than half completed, the fundus suddenly left the operator's hand and with *a distinct snap* resumed its normal position. As soon as the fundus had been restored the patient rallied, and expressed herself as feeling immensely relieved. No further difficulty ensued, and recovery was rapid and complete.

Causation.—The cause of inversion in this latter case is sufficiently evident: the placenta remaining adherent, the shortness of the cord rendered inversion of the uterus on snapping of the funis inevitable. In the first case the reason for the accident is more difficult to assign; there is no ground for supposing that it was in any way due to unskilful removal of the secundines, as this was accomplished with great care, and as, moreover, serious symptoms did not set in until some minutes had elapsed. The most probable explanation is the following. The tissues of the patient, exhausted by starvation, diarrhœa, and vomiting, were in a toneless, flabby condition, and the uterus was thus prepared for inversion after the method described by Dr. J. E. Taylor, which consists in a rolling out of the cervix with gradual implication of the body and fundus. As long as the placenta remained in the vagina the lower uterine segment was to some degree supported, but with the removal of the afterbirth all obstruction to the completion of the accident was taken away, and in a few minutes complete inversion had become established.

Reposition.—In neither case was any obstacle to reposition offered by the tissues of the cervix or lower uterine segment. In Case 1 the fundus was the only part which proved difficult to replace; it seemed to be the only part of the uterus which maintained a degree of retraction, and the existence of this latter is an argument against the hypothesis that the process of inversion could have commenced at the fundus. In Case 2 one feature is full of interest—viz., the readiness with which the fundus *reinverted itself* after once Mr. Fairles had started the process. Cases of spontaneous restoration of a completely inverted uterus have been observed by various physicians, and the behaviour of the viscus during reposition in Case 2 goes far to confirm the correctness of such observations.

Montagu-square, W.

AT the annual meeting of the governors of the Dundee Royal Infirmary on the 13th inst., satisfactory reports were presented and adopted.

THE members of the medical staff of Jervis-street Hospital, Dublin, on the 18th inst. entertained a number of the friends and supporters of the hospital to breakfast. The visitors were afterwards conducted over the institution.

ST. MARY'S HOSPITAL.

A CASE OF GALL-STONES IN THE CYSTIC DUCT; CHOLECYSTOTOMY; RECOVERY.

(Under the care of Dr. BROADBENT and Mr. PAGE.)

THE operation of cholecystotomy has not yet been performed in so many cases as to deprive of considerable interest the record of a successful case. The following is an example of the operation in which, after previous tapping of the gall-bladder, with only temporary relief and with no ill effect to the patient, stones were removed from the cystic duct which without surgical aid could not have been passed. The after progress of the case was all that could be desired. For the notes we are indebted to Mr. P. A. Lloyd, house-physician.

S. W——, aged thirty-three, was admitted under Dr. Broadbent on Jan. 24th, 1887, complaining of a tumour in the region of the gall-bladder. In April of last year she had an attack of what appears to have been biliary colic, though she had no jaundice, and did not pass a gall-stone per rectum. Shortly after this attack the swelling was first noticed, though it caused no inconvenience till Christmas, when the patient began to feel a dragging pain in the right side, especially after exertion. No further history of colic, nor any history of jaundice, could be obtained, but the patient said she was subject to "bilious attacks" from time to time.

On admission, there was a swelling in the region of the gall-bladder, about the size of an orange, which was smooth, hard, and freely movable. No enlargement of the liver could be discovered.

On Feb. 13th six ounces of slightly opaque fluid were drawn off by aspirator. The fluid was faintly alkaline, sp. gr. 1008, and contained about one-tenth albumen. No hooklets or echinococci could be discovered on microscopic examination. After the tapping the tumour could no longer be felt, and the patient left the hospital ten days later, free from all symptoms. On March 17th she was readmitted, as the cyst had again filled; she had felt the pain in her side during the previous week. On March 31st the tumour was again aspirated, and eight ounces of fluid were drawn off, of a pale green colour, faintly alkaline (sp. gr. 1010), and containing mucin and about one-sixth albumen. Microscopic examination showed only a few blood-corpuscles, small masses of yellow pigment, and a few epithelial cells. On April 3rd the cyst had once more refilled to its former size. Dr. Broadbent now considered that the tumour was a distended gall-bladder, and not a hydatid, as had at first been suspected. Mr. Page was therefore asked to perform cholecystotomy.

On April 9th, chloroform having been administered, Mr. Page made a vertical incision two inches long, commencing half an inch below the ninth costal cartilage on the right side and extending down to the level of the umbilicus. The abdominal walls having been divided immediately external to the rectus, and the peritoneum opened, the gall-bladder and the edge of the liver were seen. There were some slight recent adhesions between the gall-bladder and the parietal peritoneum. The cyst, having been carefully examined, was then aspirated, and ten ounces of purulent fluid drawn off. The empty gall-bladder was now seized with forceps and incised; its cavity was wiped dry with sponges and then explored by the finger. A stone about the size of a walnut was felt in the cystic duct, and removed with a pair of small lithotomy forceps. Two minute calculi were afterwards detected, and were removed on a sponge. There was no discharge of bile-stained fluid after the removal of the calculus. The walls of the suppurating cyst (i.e., the distended gall-bladder) were now fixed by catgut sutures to the abdominal wall, and a large drainage tube was passed as far as possible towards the cystic duct. Wood-wool pads formed the dressing, and perchloride of mercury was the antiseptic used. The fluid removed had a specific gravity of 1012, was alkaline, and contained a large quantity of pus. When the pus had settled the supernatant clear fluid contained about half albumen, and gave Gmelin's and Pettenkofer's tests for bile-pigments and acids.

The wound in the gall-bladder healed in five days, and that in the abdominal walls in about five weeks. There was neither pain nor rise of temperature after the operation, and no bile was discharged through the wound. The patient left the hospital on May 17th, with no trace of tumour, and quite free from abdominal discomfort, and there has been no reappearance of the swelling up to the present time.

HAMPSTEAD HOME HOSPITAL.

CHRONIC RENAL ABSCESS; ABDOMINAL NEPHRECTOMY; RECOVERY.

(Under the care of Dr. HEATH STRANGE and Mr. EDMUND OWEN.)

E. M——, widow, aged thirty-seven years, a domestic servant, was admitted Feb. 15th, 1886. Her father and two of her brothers had died of phthisis. As a young woman she had been the subject of hæmaturia, and during married life her urine had contained blood from time to time, but from 1877 to 1886 the urine had been, so far as she knew, quite normal. Twelve months before admission she found that she got easily tired after exertion; although the urine was normal, she had frequent desire to pass it. The chief cause of her coming into the hospital was the pain which she had in her legs (which were much wasted). She complained also of great debility—indeed, she was unable to stand. Dr. Strange observed a tumour in the left side of the abdomen, which, the patient said, had increased rapidly in size. It appeared to be about the size of a cocoa nut, and was evidently renal in origin. She bore physical examination well, but fomentations had to be occasionally applied over the region of the tumour for the relief of pain. She lay prostrate in bed. She passed her urine but twice in the twenty-four hours; it averaged twenty-eight ounces, specific gravity varying from 1010 to 1028; it contained neither pus, blood, nor albumen; in fact, during her stay in hospital it was normal, but scanty.

The diagnosis was made of cystic disease of the kidney, and removal of the tumour by abdominal section was advised; it seemed too large to be brought away entire by the post-peritoneal or lumbar operation. There were two unfavourable elements as regarded prognosis: the woman was in a very feeble state of health, and the other kidney, though not tender, was evidently larger than natural. Sir Spencer Wells—one of the consulting surgeons to the institution—saw the patient with Dr. Strange and Mr. Owen, and agreed that the tumour should be removed by abdominal section; he kindly arranged also to be present at the operation, which was performed on May 18th by Mr. Owen, Dr. Strange and Dr. Percival Cockey assisting, and Dr. Pidcock administering the anæsthetic. The abdominal cavity was opened through the left linea semilunaris, the posterior layer of the peritoneum being opened on the outer side of the descending colon, so that the kidney might be reached without interference with the branches of the inferior mesenteric artery. The renal vessels were so small that it was at once evident that they were supplying an organ unusually poor in vascular tissue. Their size confirmed the diagnosis of cystic disease. Had they been associated with a malignant growth they would have been larger than normal. They were tied with carbolised gut, which was then cut short. The ureter was tied in two places and divided, and as the section showed a drop of pus, the lining of the tube was scraped clean and touched with iodine. The bed from which the tumour was removed was washed out with a warm and weak solution of mercuric chloride, and the laceration in the posterior layer of the peritoneum was closed with sutures of fine gut. No drainage tube was used. The abdominal wound was also sutured with gut, and dressed with thick pads of sublimate wool and a flannel binder.

For eight days after the operation the temperature remained at normal, but after this it was raised for three days, on one occasion reaching 101°F., but it descended immediately after a small collection of blood and serum was dislodged from the wound; and until she left the hospital

Digitized by Google

on July 3rd, the chart was not marked above the normal line. After leaving the hospital she was so well and strong that she was able to enter domestic service again as a cook.

The tumour consisted of the thickened fibrous tissue of the kidney, in which were a number of large and small cysts which contained ten ounces of creamy pus, of a pale green tint; it was not examined for bacilli. Before operating, the tumour seemed too large to come readily by the loin; but when it was exposed it was evident that the retro-peritoneal operation would have served; the cyst walls, moreover, were so tough that they probably would not have burst during the extraction. It was about the size of a very large fist.

The patient was afterwards admitted into St. Thomas's Hospital under the care of Dr. Harley in May last, and we are indebted for the report of her condition at that time to Mr. H. J. M. Montague, house-physician. She complained of a tumour in the right side, which pained her very much on movement, becoming much more painful after she had been walking about for some time; she also complained of pain in the left lumbar region. On examination, a scar was found in the left linea semilunaris, at the seat of which there was a hernia. In the right lumbar region was a smooth rounded body, quite movable, and slipping under the liver on manipulation; tender to pressure, but not causing nausea when pressed upon. Diagnosis: Healthy movable kidney; urine of high specific gravity, with a large deposit of urates, no albumen. Uric acid crystals were seen under the microscope. The other organs were healthy.

The kidney became less painful, and the patient left the hospital wearing an abdominal belt.

GENERAL HOSPITAL, BIRMINGHAM.

CASES OF OVARIOTOMY.

(Under the care of Dr. MALINS.)

CASE 1.—A. H——, aged thirty-five, married. Admitted on Feb. 4th, 1886. Multiple cyst of left ovary, with fluid of varied consistence. Weight 240 oz. Adhesions to anterior abdominal wall and to right broad ligament and Fallopian tube. Right ovary enlarged to about four times its normal size, with numerous cysts; removed also with corresponding tube. Pedicles transfixed and tied with silk. Keith's drainage tube used. Recovery.

CASE 2.—J. T——, aged forty-four, married. Admitted on March 2nd, 1886. Multiple cyst of right ovary. Large cyst containing porter-like fluid and papillomatous growths inside. Adhesions to anterior wall of abdomen. Pedicle short; transfixed and tied with double silk close to uterus. Use of Keith's drainage tube; removed on the evening of the 4th. Recovery.

CASE 3.—E. P——, aged forty-three, married. Admitted on May 27th, 1886. Multiple cyst of right ovary. One large cyst containing twenty-seven pints of brown viscid fluid; solid. Weight 85 oz. No adhesions. Good pedicle, transfixed and tied with double silk. Quantity of ascitic fluid. Keith's drainage tube employed; removed on the 30th. Subsequently, continued sickness and quick pulse; average temperature 100·4°. Later, some tympanites. Died on June 7th from peritonitis.

CASE 4.—C. G——, aged forty-nine, married. Admitted on Sept. 2nd, 1886. Multiple cyst of left ovary. Very thick walls, undergoing myxomatous degeneration. Weight of liquid contents, 180 oz.; solid, 37 oz. Fair pedicle; transfixed and tied with double silk ligature. Recovery.

CASE 5.—M. W——, aged fifty, married. Admitted on Sept. 30th, 1886. Dermoid cyst of left ovary, containing hair, bone, and two teeth. Pedicle sessile; transfixed and tied with silk. Weight of cyst, 10¼ oz.; of contents, 36 oz. Opposite ovary enlarged; also removed. A fibroid tumour at right angle of uterus; transfixed and tied with double silk ligature and removed. Weight 6½ oz. Keith's drainage tube employed; removed on the morning of Oct. 2nd. Recovery.

CASE 6.—C. H——, aged thirty-six, single. Admitted on October 21st, 1886. Multiple cyst of left ovary. Weight: fluid, 120 oz.; solid, 42 oz. Papillomatous growths inside. Right ovary irregularly shaped, enlarged about three times the normal size; filled with pellucid cysts; removed. Some pelvic adhesions. Pedicle of first sessile; transfixed and tied with silk. Pedicle of second longer; transfixed and tied. Peritoneum velvety and vascular; some ascitic fluid. Keith's drainage-tube used; removed on the 28th. Recovery.

CASE 7.—E. P——, aged forty-four, married. Admitted on November 4th, 1886. Large multiple cyst of left ovary, undergoing interior degeneration. Some adhesions to small intestine. Good pedicle; transfixed and tied. Drainage tube used. Recovery.

CASE 8.—J. H——, aged thirty-three, married. Admitted on November 13th, 1886. Large unilocular cyst, containing 206 oz. of clear, slightly viscid fluid. Some solid matter at base. No adhesions; short pedicle; transfixed and tied with silk. Recovery.

CASE 9.—J. P——, aged twenty, single. Admitted on December 30th, 1886. Dermoid cyst of left ovary; globular; containing a quantity of hair and about 12 oz. of oily liquid at temperature of body, solidifying in open air. Weight of cyst, 4½ oz.; thick walls; base tied in two parts with silk below cyst. Recovery.

Remarks.—The above cases represent the number of ovariotomies performed in the year 1886 at the General Hospital as they were admitted, without selection. The one death was in a feeble emaciated woman, who made a good struggle for life, but succumbed to peritonitis twelve days afterwards. The tumour was very large, and the health much impaired before admission. Keith's drainage tube was used in the majority of cases, being removed when the fluid drawn through it became clear and free from blood. The operations were done singly in an isolated ward with special nurses, no precautions beyond stringent cleanliness being observed. The peritoneum was washed out when there had been fluid in it with a solution of boracic acid in warm water, with a glass tube, and glass funnel connected by a piece of indiarubber tubing, as little handling or sponging as possible being always observed.

Medical Societies.

OPHTHALMOLOGICAL SOCIETY.

Uniocular Optic Atrophy and Temporal Hemianopsia.—Permeability of the Suspensory Ligament by Organised Substances.—Choroido-retinitis.—Cyclotomy in Glaucoma.

AN ordinary meeting of this Society took place on the 9th inst., Mr. J. W. Hulke, F.R.S., President, in the chair.

Mr. STORY read a case of Optic Atrophy in one eye, with Temporal Hemianopsia in the other, occurring in a young woman, a dressmaker, who gradually lost her sight in one eye, and partially in the other. The menses were irregular. As had been observed in similar cases of tumour of the pituitary body, the patient grew much stouter. Headache and giddiness were complained of, but the sight improved, and though the optic atrophy remained, she was enabled to follow her occupation.—Mr. NETTLESHIP remarked that a very similar case had been recorded in the Society's Transactions, and in that instance, after death, a tumour was found in the pituitary fossa. Other similar cases had been published, and he had lately seen a case at St. Thomas's Hospital where the same train of symptoms had been produced in the same way.—Dr. HILL GRIFFITH said that he had placed on record a case identical with that of Mr. Story. Cessation of menstruation and sleepiness had been present in his case; and in several cases that he had seen the patients had complained of getting stout.—Dr. JAMES ANDERSON briefly described the case he had published, which closely agreed with that of Mr. Story. He said that it was the rule in pituitary tumours that the patient should get very stout.—Dr. COUPLAND mentioned also the concurrence of an increased development of tissue in conjunction with disease or enlargement of the pituitary body—a condition known as "acromegaly" (*vide* THE LANCET, p. 1195).

Dr. HILL GRIFFITH read a communication on the Permeability of the Suspensory Ligament by Organised Substances. He mentioned several cases of keratitis punctata without any iritis, but with recent patches of choroido-retinitis, and also two cases of retinal gliomata, with separate nodules free in the anterior chamber, and showed naked-eye and microscopical specimens. He endeavoured to show from these two groups of cases that solid particles were carried by the nutrient currents through the zonule at the circumlental space.—Mr. JESSOP mentioned a case of an old opaque lens in which, on opening the eye, a gush of cholesterine

Digitized by Google

spangles came from above behind the iris, and fell to the lower part of the anterior chamber, taking up a triangle with the apex upwards. The cholesterine was so large in quantity that it must have come from the vitreous.—In reply to Mr. Marcus Gunn, Dr. HILL GRIFFITH said that in his case there was evidence of choroiditis, gradually passing into atrophy of the usual description.—Mr. LANG, who showed a specimen, with the suspensory ligament *in situ*, said that he was much interested in the association of solitary patches of choroiditis with keratitis punctata, and he thought that the two conditions were always associated; the cases were more frequent in young women, but occurred also in young men. The etiology was obscure. The vision was not much affected when the cases were first seen.—Mr. NETTLESHIP partly agreed with Mr. Lang as to the presence of isolated patches of choroiditis in a large number of cases of keratitis punctata. Opacities of the vitreous were often present, and were sometimes found even when there was no choroiditis, and in some only the keratitis punctata could be seen. The dots on the back of the cornea could only be explained on the hypothesis that there had been migration through the suspensory ligament.—Mr. J. B. STORY could not accept this view, as it would not explain those cases where there was no keratitis punctata. He thought it was very difficult to exclude the theory that there was some cyclitic deposit.—The PRESIDENT thought another explanation was possible apart from the mechanical transfer theory. There might be an inflammatory process, and cyclitis or choroiditis, or both, expressive of some general conditions. Some of the spots were only flocculent precipitates or coagula lying loosely; some might be due to proliferation and disintegration of the epithelium. The anatomical difficulties in regard to the mechanical convection theory appeared to him to be very great.—Mr. SILCOCK mentioned the case of a lady in which a punctate appearance at the back of the cornea was associated with opacities in the vitreous, but without choroiditis.—Mr. MACKINLAY observed that he was unable to detect the spaces in the suspensory ligament, even with powerful lenses.—Mr. HUTCHINSON, jun., argued that a transmission of particles might take place in a direction the reverse of the ordinary, as there was reason to believe happened in cases of secondary infection from axillary tumour.—Mr. W. J. COLLINS suggested that particles might pass along the canal of Stilling, and thus the necessity for supposing that they traversed the impervious hyaloid membrane would be obviated.—Dr. HILL GRIFFITH said he was much gratified by the excellent discussion that had taken place, it would not be necessary for him to take notice of all the points mentioned. He had, like Mr. Nettleship, seen cases of descemetitis without iritis, in which he had failed to make out choroiditis, the cases he had recorded were only made out to support the proposition contained in the heading of the paper, and were but put forward as examples of the most usual conditions met with in descemetitis. To Mr. Story's objection that choroiditis did not always produce descemetitis, he would reply that cystitis was not always followed by that condition. He would not accept Mr. Hulke's explanation of a coincident cystitis to account for his cases, for here, as in diseases of the nervous system, we should avoid a "double lesion" if one be sufficient to account for all existing symptoms.

Mr. BRAILEY narrated a case of successively occurring Isolated Spots of Choroido-retinitis affecting the yellow spot region of an independent gentleman, aged forty-one, who had been under observation seven months and a half, during which period he had five times experienced the development of a small relative scotoma at or near the centre of the field of vision of the right eye, which was wearing its full correction (+3·50 sph. and +1 D, cylinder). His left eye had been absolutely blind from glaucoma for twenty years, and was still hard, though painless. The scotomata, as appreciable by him at eighteen inches, varied in size from two to six inches square. Each appeared as a round or oval disc of dim and troubled vision, surrounded by a bright, glittering edge. At first the disc was well marked with annoying dimness and distortion of objects, which appeared materially darkened when embraced in its area. Printed letters appeared diminished as well as huddled together. Distant vision, though it might be diminished even to one-half in a moderate light, was not much affected with bright light, whether natural or artificial. All colours, except perhaps green, were dulled as if dashed with grey. Soon the spot began to amend, and was more translucent, giving to his sight the impression of an interposed disc of neutral tinted glass whose sharp edge slightly glistened in places. Each spot had resulted in almost perfect restoration of vision, as estimated by test types, though the ophthalmoscopic appearances still persisted to some degree. Ophthalmoscopically, each scotoma corresponded to a small, rounded, isolated, not well defined spot of dull greyish colour. Most of them were in close relation to, though clearly on a lower level than, the retinal bloodvessels, which were also decidedly larger than usual. The optic disc was slightly hazy at its margin, but of normal colour. An ophthalmoscopic drawing showed three of the spots—one moderately recent, and two in process of fading.—Mr. WARREN TAY considered the case in some respects unusual, and said that the retina must have been damaged.—The PRESIDENT remarked that, being an artist, the patient could observe and describe with great accuracy.

Mr. G. E. WALKER read the sequel to the case of Cyclotomy in Glaucoma. He also showed a young man with pulsating exophthalmos in process of cure. He had been shown at the November meeting, when the symptoms were much more marked. The disease had been caused by his fall down some cellar steps on to a flagged floor in January, 1886; this produced insensibility for three days, and on awakening, the boy found he had a swishing noise in his head. No ocular symptoms became manifest until July, when engorgement of the right eye appeared, and a fortnight later, of the left. In a day or two the noise disappeared, and the proptosis of the right took place. This increasing, he had proposed to tie the carotid artery, as he believed a true aneurysm of the artery, where it passed up from the cavernous sinus, had been produced. [illegible] on account of the opinion of two gentlemen who believed it was not true aneurysm, but an opening of the carotid into the cavernous sinus, the operation was not performed. From October to the end of January the general symptoms appeared to be stationary, but at that time (Jan. [illegible]) he was much frightened by being caught in a crush at a theatre, and soon afterwards found the bruit had returned. The extrusion of the eye, its engorgement and pulsation at first were considerably increased, but afterwards decreased at first rather quickly, and since then very slowly. He contended that, although in this case a happy result had been brought about by an accident, it would be [illegible] future case to tie the carotid, and not to trust to the [illegible] of accidents; and he gave a short account of a case in which he had performed the operation with complete restoration of the use of the eye, although at the time of operation it was lying on the cheek, thrust out from [illegible] the lids, and with mere perception of light.

The following living and card specimens were [illegible]. Mr. Silcock: Kerato-iritis in a woman probably the result of congenital syphilis. The peculiarity of the case consisted in the presence of a number of minute dots situated on the surface of Descemet's membrane or in the superficial layers of the cornea, and arranged in the form of a ring which corresponded in position with the pupillary margin of the iris. The affected cornea also presented the characteristics of interstitial keratitis. The cornea of the other eye was not affected. Mr. Cross: (1) Tumour of the orbit, probably sarcomatous, in connexion with which Mr. Cross mentioned a case which he treated by shaving off the growth, free application of nitrate of silver, with the result of which had so far not been followed by a recurrence. (2) A case of Opaque Nerve Fibres, limited to the Papilla. Mr. J. Collins: Extensive Hæmorrhage into a Blind Eye. Coarctation of Retina. Mr. Lawford: Coredialysis. A complete Anteversion of the detached portion. Mr. Story gave an experimental demonstration bearing on the Pathology of Glaucoma.

ACADEMY OF MEDICINE IN IRELAND.

Distribution of Phthisis and Diseases of the Respiratory Organs in Ireland.

AT a meeting of the Sub-section of State Medicine on May 19th,

Dr. T. W. GRIMSHAW (Registrar-General for Ireland) read a paper on the above subject. The total number of deaths in Ireland during the decade was 966,745, of which phthisis caused 103,528, or more than one-tenth; other diseases of the respiratory organs 142,091, or nearly

Digitized by Google

sixth—the two groups taken together causing more than one-fourth of the total mortality of Ireland. Lung disease was, therefore, the most important element in considering questions connected with the health of the people of Ireland. The main conclusions arrived at by Dr. Grimshaw were that the less civilised portion of the population of Ireland were less affected by phthisis and lung disease than the more civilised portion of the community; that not only was phthisis more prevalent among urban than among rural populations, but that essentially rural populations near large towns suffer more than those in remote districts, thus pointing to infection as a means of spreading the disease. Comparing the distribution of phthisis with the physical configuration of the country, it was found that, as elsewhere, the low levels suffered more than the high levels. The bogs do not seem to specially favour the prevalence of phthisis; indeed, they seem rather to counteract the disease. There was no constant relation between the prevalence of phthisis and other forms of disease of the respiratory organs. In many cases there is an absolute contrast between the prevalence of phthisis and the other forms of lung disease. There did not appear to be a close relation between the general distribution of the geological formation and the prevalence of either phthisis or other forms of lung disease, except in so far as geological formation influenced elevation, &c.—Sir CHARLES CAMERON said the subject opened a vast domain for investigation to those interested in the etiology of disease. It was remarkable that there seemed to be a greater prevalence of the diseases in question on the eastern than on the western seaboard. Dublin occupied a bad position of eminence in the order of mortality—exceeding, as it did, even Belfast, where, on account of the flax manufactures, diseases of the respiratory organs might be expected to abound. The death-rate would be a means of comparing the salubrity of the different districts.—Dr. CHARLES MOORE, referring to Dr. Grimshaw's observation that sudden change was apt to produce bronchitis, said there was no country where there was greater suddenness of change of temperature than Egypt, and yet it was a common thing to send people to Egypt to be cured of phthisis. The drainage question was important in Dublin, where the subsoil water had greatly increased since the disuse of pumps. Many years ago Sir William Wilde drew attention to the prevalence of phthisis round the coast of Ireland. The Bog of Allen and other bogs in the centre of Ireland were factors which favoured phthisis. So also did crowded populations. In the Zoological Gardens, Phœnix-park, phthisis prevailed amongst the monkeys.—Dr. COSGRAVE adverted to the observations of Dr. M'Neill, medical officer of the Gesto Hospital, Isle of Skye, as indicating that consumption was communicable from one person to another.—The CHAIRMAN pointed out that the rule that large cities favoured the prevalence of consumption found a remarkable exception in London, where the disease was below the average, except in the eastern districts. Turning to Ireland, there could be no doubt that the large towns acted as foci from which pulmonary phthisis seemed to spread. He agreed with Dr. Grimshaw that rainfall had very little to do with the matter as regards Ireland. He did not agree with Dr. Charles Moore as to the pernicious effect of the Bog of Allen. His opinion was, on the contrary, that large peat districts perhaps tended to control phthisis by acting antiseptically. The distribution of bronchitis in the south of Ireland was most puzzling, and he was at a loss to explain it.—Dr. GRIMSHAW, in reply, said, with regard to Kilmallock, it was curious the mortality from bronchitis appeared to indicate rather a healthy condition of the population. The number of old people who died there from bronchitis was extraordinary, and the great majority of the bronchitis cases were returned as from the Kilmallock Workhouse. The disease was not, in fact, strictly speaking, bronchitis, but the bronchial effusion of old age. Of course that depended on how the certificates were given. The effect of drainage was well known in diminishing phthisis, cholera, and typhoid fever. It was, however, always a question as to whether drainage diminished the phthisis death-rate. For his own part, he was inclined to think that it acted indirectly by improving the general health of the people, and by diminishing the prevalence of pneumonia, which was one of the principal foundations of phthisis, and also by diminishing the prevalence of typhoid fever. The drainage of towns was not a question of the drying of soils so much as the getting rid of dirt and sewage matter. How much was due to the drying of the soil itself, or how much to getting rid of dirt, it was impossible to say, or to explain which was the main factor of disease. With a perfect system of sewerage in Dublin and the dirt kept out of the Liffey, and a clean gravel bed in the centre, the public health would improve. When cholera prevailed in Pembroke township district there was practically no cholera in Rathmines, the reason being that Rathmines was dry, while Pembroke was waterlogged, having a gravel bed with the clay below it like a sponge in a basin. Sir William Wilde had mentioned that the prevalence of phthisis along the eastern coast was specially referable to the general conditions of life. Unfortunately, when he made his observations he had as reliable data very few facts, there being then no machinery for registration, and the only evidence being hearsay. As to the bogs, he was of opinion that a bog was a totally different thing from a marsh, so far as the health of the community was concerned. The most familiar example in proof was that ague prevailed in the marshy lands of England, but it never occurred in a marshy bog. What the antiseptic property of peat was he did not know, but that it was antiseptic there was no doubt. Many examples of the antiseptic properties of bog had been observed. The presence of phthisis in the animals in the Zoological Gardens was due, he had no doubt, to their eating tuberculous food.

Notices of Books.

The Treatment and Utilisation of Sewage. By W. H. CORFIELD, M.A., M.D. (Oxon.), Fellow of the Royal College of Physicians, London; Professor of Hygiene and Public Health at University College, London, &c. Third Edition. Revised and enlarged by the Author and LOUIS C. PARKES, M.D. Cert. Public Health Lond. London: Macmillan and Co. 1887.—A third edition of this well-known and valuable work was much needed, and it has been satisfactorily executed. The first edition appeared in 1870, and the second in 1871. Much additional experience has since been gained, and many elaborate inquiries have been carried out, but it is to be feared that very little real progress has been made. The obstinate persistence of the Metropolitan Board of Works in their erroneous treatment of the sewage of London has indeed produced a searching and satisfactory inquiry by a Royal Commission; but as the Board still persists in disregarding the most important of the recommendations of the Commissioners, the great problem cannot at present be solved in London. In evidence of the little real advance made in our knowledge, we find that the summary with which Prof. Corfield concluded his first edition is now reprinted entire and without addition, the present authors remarking that they see no reason to alter it. It must not, however, be supposed that the bulk of the book is left unaltered. On the contrary, all the experience gained in England and abroad during the last sixteen years is well chronicled. Thus we have the Croydon experience in regard to the ventilation of sewers, an account of the Liernur system, the Berlier system (partly adopted in Paris), and the Scott system tried at Ealing. We have also critical descriptions of the many precipitating schemes which have from time to time been tried, and a full account of the results of the labours of the Royal Commission on Rivers Pollution and on Metropolitan Sewage Discharge. Altogether it will be seen that the book well maintains the reputation of the author. It is in fact essential to every sanitarian.

Grundriss der Bakterienkunde. Von Dr. Med. CARL FRAENKEL. Berlin: A. Hirschwald. 1887.—The author of this handbook on bacteriology can claim to speak with authority, since in his capacity of assistant in the Hygienic Institute of Berlin University he has frequently had the conduct of those monthly courses of instruction which Professor Koch has so successfully established. The book is intended to furnish all the details necessary to be borne in mind in laboratory work, but it includes more than a de-

Digitized by Google

scription of technical methods. These form about one-half of the volume, the remainder being descriptive of the morphological and physiological characters of micro-organisms. The absence of illustrations is compensated by the clear descriptions given by the author, and as the book is one especially for laboratory work, there is no absolute necessity for elaborate illustration. The subject matter is most systematically arranged, and presented in the form of lectures, or rather demonstrations with oral exposition. They will doubtless serve as a model for bacteriological instruction in similar institutions.

What can a Mother do to preserve her Children's Teeth? By HENRY C. QUINBY. Liverpool: G. G. Walmsley.—The above is the title of a useful pamphlet designed to take its place amongst the books on domestic medicine. The author gives clearly and in a popular form the reasons for the necessity of attention to the health of the deciduous teeth, a subject which has been frequently mentioned in these columns. With regard to patients seeking professional advice for their children, it seems to be a frequent occurrence that they do not expect to pay a fee unless some operation is performed; and he rightly urges that this temptation should not be put in the way of the dentist, and that, in fact, advice is quite as valuable; nay, more so, than taking out a temporary tooth or putting in a dressing. There is a good deal of useful information cited such as the deformity that may be produced by thumb-sucking, and the mistake so constantly made of believing the six-year molar to be one of the temporary set. Most of the views expressed are those generally accepted by the profession, although exception must be taken to some of them; for instance, Mr. Quinby objects to any tooth-brush the bristles of which are harder than horsehair; also he does not advocate the filling of temporary teeth of which the pulps are dead, thus leaving fetid food traps with the almost certainty of decay of the contiguous teeth. He, however, goes a little too far with amateur doctoring when he expects a mother not only to diagnose between toothache due to an inflamed nerve and that caused by periostitis, but in the latter case to drill into the pulp cavity to let out its fetid contents.

Travels in the Interior. By LUKE THEOPHILUS COURTENEY. Edited by a London Physician. London: Ward and Downey.—"A London Physician," in the preface to this book, states that he found the above story in manuscript on his table one morning after the departure of his patients. Thinking the method of teaching physiology ingenious and finding no owner, he resolved to publish it. The plot may be given briefly. Belinda Courteney, her brother (who is a M.R.C.S.), and a friend accompany the uncle, Captain Courteney, to Trebizonde, where they purchase in the bazaar a box of pills capable of reducing them to the smallest dimensions from an old woman who repeats a rhyme to them to the effect that in order to regain their natural size it is necessary to place a grey hair between the teeth. They have scarcely time to reach the room where the uncle sits before they become almost microscopic, and are whisked up by him with his eye-glasses, and fall thence into his mouth. This they explore fully, afterwards passing into the throat and climbing into the Eustachian tube. The description of this is picturesque, the cilia being compared to ripe corn waving in the summer breeze. Phil, the brother, advises Belinda always to breathe through her nose, and remarks that when on night duty in his hospital ward he counted two hundred patients sleeping with their mouths open; a large proportion of these patients suffered from lung diseases. The three young people next pass into the stomach and observe the digestive process. Finally, they ascend by the thoracic duct and are introduced into the venous system. They then work up a small vein and emerge through a pimple. Placing a grey hair between their lips, they return to their normal size. There is a curious slip near the beginning of the book, where Phil (a M.R.C.S.E.) is described as a lad of eighteen. The interior is seen by means of a portable electric lamp, and Phil is supplied with numerous unknown inventions for the maintenance and comfort of life. The book is ingenious and amusing, and may serve to impress some of the leading facts of physiology on non-professional readers.

Variations of Fortune. Illustrated by sketches of some old towns of Italy, and those who influenced them. London: Sampson Low, Marston, Searle, and Rivington.—Those who travel in Italy, either for health or pleasure, may find some interest in the above book. It is quietly and thoughtfully written, and contains an account of Miguel de Molinos, the famous Quietist, who was condemned by the Inquisition to perpetual imprisonment. A curious method of payment to a doctor is related in an old Italian document. The family of Signorelli, the painter, were ill of the plague, and about this time an agreement was made between the doctor and the painter "that for services received, and for those which Luca Signorelli hopes to receive from Dr. Luigi de Rutania, a Frenchman settled in the town of Montone; he had painted a picture gratuitously for a chapel built by the doctor, and dedicated to Santa Christina in the church of S. Francisco at Montone, the said Luigi de Rutanis promising to attend without fees on Luca Signorelli, or any of his family, when ill in the future."

ROYAL SOCIETY.

Note on the Functions of the Sinuses of Valsalva and Auricular Appendices, with some remarks on the Mechanism of the Heart and Pulse.

ON Thursday, the 16th inst., Mr. MAYO COLLIER read on the above subject a paper which may be thus summarised. The object of the paper was to disprove the present apparently accepted idea that the sinuses of Valsalva are mere bulgings of the arterial walls, formed by a reflex current, induced by the sudden closure of the semilunar valves. The existence of a reflex current was shown to be impossible, and the theory of the sudden opening and closure of the semilunar valves was disproved. The presence of the sinuses of Valsalva was shown to be an absolute essential to the mechanism of the heart's action. The paper then treated of the action of the auricle and the part played by the auricular appendix, the latter being considered as the only part of the auricle that sensibly and vigorously contracts. The causes of the first sound of the heart were next alluded to, and the theory that the closure and vibration of the tricuspid and mitral valves assist in its production was refuted. The mitral and tricuspid valves do not close suddenly, and anything like an audible vibration of these structures, or the chordæ tendineæ, was shown to be impossible. The action of the ventricle and the mode of its injection into the aorta were dwelt upon at some length. The latter part of the paper was devoted to the mechanism of the pulse, and an explanation was given of the so-called dicrotism. The following is a summary of the chief points of the conclusions arrived at:—1. The sinuses of Valsalva are absolutely essential to the mechanism of the heart's action. 2. The musculi papillares serve the same purpose for the auriculo-ventricular valves as do the sinuses of Valsalva for the aortic. 3. The auricular appendices complete the distension of the ventricles without appreciably altering the general tension in the auricles. 4. The first sound of the heart is not due to nor influenced by the closure or tension of the tricuspid and mitral valves. 5. The semilunar valves open and shut gradually, the second sound of the heart being due to the sudden difference of pressure on the two sides of the valves at the moment of commencing diastole of the ventricle, causing them to vibrate. 6. At each systole the contents of the ventricle distend only a segment of the length of the aorta, the force of the ventricle exercising no influence directly on the general circulation, but indirectly by the elastic recoil of the aorta. 7. That the pulse is due to a wave of dilatation and recoil, which wave is normally single. 8. That when the arterial tension is below a certain standard one or more secondary pulse waves can be frequently felt, due to a redistension of the penultimate section and its consequent repeated recoil.

THE LANCET.

LONDON: SATURDAY, JUNE 25, 1887.

No class or section of Her Majesty's subjects rejoices with greater sincerity, or better reason, in the fruition of a happy and illustrious reign than does the medical and surgical profession. Under the benign influence of that progressive peace and domesticity which, in spite of many regrettable interruptions, have characterised the administration of State affairs in this country since VICTORIA came to the throne, the eminently peaceful arts of medicine and surgery have flourished exceedingly; they have attained a very high development, and, which is more important, they have been consolidated and securely based on the cognate sciences with which it may be confidently affirmed they are now indissolubly associated. It cannot be doubted that the scientific arts to which we as a profession are devoted, in common with the arts of peace in general, owe much to the providential fact that the crown of England devolved on a female Sovereign at the particular conjuncture when VICTORIA came to the throne, and that its wearer has been a woman in whom the highest virtues have been combined with the purest and truest love of home and family happiness which has been manifested in the life of any monarch that ever sat on the English throne. The spirit of our national life has been one of quietness, albeit, as we have said, there have been painful outbreaks of those baser passions and that greed of conquest which lie beneath: and the long spell of comparative tranquillity we have enjoyed has given space for the growth of that peaceful and peaceable stability on which the permanent prosperity of every nation must in the long run depend.

We have no thought of reviewing the progress of medicine during the reign of VICTORIA. To do this in the most cursory way would require much greater space than we are able to devote to the subject. Meanwhile, there are one or two reflections which it may be worth while to offer for the consideration of our readers in this week of jubilee.

The profession may be congratulated on the immense progress which has been made in developing the sciences of medicine and surgery, and especially in the development of two almost new branches of knowledge during the last half century. Turning to the Students' Number of THE LANCET for 1833 we find this significant remark: "In the medical department of the London University" (which was at that date a *teaching* university in Gower-street), "the student will find there are two subjects engaging the attention of two celebrated Professors which are not taught in the other academical establishments; we allude to the lectures on *Comparative Anatomy* by Professor GRANT, and those on *Morbid Anatomy* by Professor CARSWELL. ..... We have selected for especial notice the lectures of Professors GRANT and CARSWELL, as we find that comparative and morbid anatomy are subjects which do not appear to be entitled to the notice of the rulers in our chartered Colleges and Halls." To the "University of London" (which we now know as "University College"), be it remembered, the profession owes the development of these two branches of knowledge as special subjects of study; and who among us can fail to perceive that out of the study of comparative and morbid anatomy has grown that physiology of medicine and surgery which is the distinguishing feature of the art of healing as we know it to-day? Physiology, properly so called, could have no real existence apart from comparative anatomy and morbid anatomy. Not merely structure but function is elucidated by the study of organic development in the light of comparative anatomy. And the inferences derived inductively from the study of development could only be corrected by the study of such departures from the normal type of structure as are found associated with disease, whether as causes or as effects. We have repeatedly called attention to the fact that mistakes may be very readily made if morbid anatomy be scrutinised without carefulness to distinguish between changes which may have been the effects of abnormal function and those which were clearly the causes and not the consequences of error in the working of the organisms wherein they are discovered; but the avoidance of this class of error is to be sought and may be found in the combined light of comparative anatomy and morbid anatomy. Therefore, we say that the debt which medicine and surgery owe to the then London University in giving these two subjects an individual existence among us cannot be overrated. A re-perusal of the introductory lecture delivered by Prof. GRANT at the opening of his course in 1833 would well repay the trouble. We venture to think that if a careful digest of all that has been achieved in medicine and surgery during the last fifty years were made and just conclusions drawn, it would be found that the progress achieved has been not only notably but almost exclusively due to the development of the two branches of knowledge especially inaugurated at the period named.

It is very interesting to note in this connexion how much we owe to the great and energetic race with which the family of our Sovereign very closely links us. We have no reason to be ashamed of our indebtedness as a nation to the infusion of that love of home life which dominates the German people, and which has done much to foster and strengthen our own peaceful disposition as a community of islanders. Nor need we try to veil or qualify the fact that to the medical *savants* of Germany we are under obligations of the largest and most practical description for contributions to the sum of medical knowledge, and in many respects for the formulation of the fundamental laws of our science and art. Her Majesty's beneficent reign has been of the highest value to medical science, as we believe it has been to our national life as a whole. Medicine has made gigantic strides between 1837 and 1887, and its progress

has been sensibly aided by—we will not say the patronage, but—the encouragement extended to its professors by the occupant of the throne, and conspicuously by the opportunity for advancement which has been afforded to all the sciences and the arts by the peaceful and enlightened influences of a period passed under the pure and happy auspices of a Sovereign who is not less loved than she is revered by a loyal and affectionate people. GOD SAVE THE QUEEN.

IT is natural that the recent researches into the nature of the contagium of scarlet fever should excite attention—both those prosecuted, on the one hand, by Dr. KLEIN in his investigations upon the relation between the Hendon disease of cattle and milk scarlatina, and, on the other, by Dr. EDINGTON in an attempt to test the value of the hypothesis on which Dr. JAMIESON had based a line of successful prophylactic treatment of scarlet fever. The disease is so common, its characters are so well marked, and its contagiousness is so striking, that it cannot be surprising to find bacteriologists keenly alive to the solution of the causes of its contagion. Nor was it likely that the researches referred to should have escaped criticism by those qualified to pass an opinion upon what is indeed a bacteriologist's question; as is to be found elsewhere in Mr. CROOKSHANK'S paper, which we publish to-day, and which was unavoidably held over last week. There is, we fear, a tendency to take sides in this matter; for it is plain that if Dr. KLEIN'S conclusions be accepted as universally true of the *materies morbi* of scarlet fever, then Dr. EDINGTON'S must fall, and *vice versâ*. We may remark here that a statement made in this journal a fortnight ago, which has been not unnaturally criticised, was not intended in the wide sense in which it was liable to be taken in consequence of the inadvertent omission of the word "such" before the word "controversy"—an omission which was overlooked in proof. We should be the last to close the door to scientific inquiry on any subject, especially one of this grave importance. There is nothing in common between the two series of results referred to, although, etiologically speaking, there is a far graver and wider issue presented in the one case than in the other. Perhaps one ground for their divergence is to be found in the distinctly different lines upon which the inquiry proceeded in each case.

Taking them in chronological order, we have first the remarkable chain of evidence adduced by Mr. POWER to prove that certain epidemics of scarlet fever traceable to infection through milk were directly related to disease in the cows yielding the milk. The facts in support of this doctrine have been slowly accumulating; and it may be remembered that some years ago Mr. POWER drew a somewhat similar conclusion in the study of the etiology of an outbreak of diphtheria. Mr. POWER has, therefore, for some time had his mind prepared for the contingency that such diseases as scarlet fever and diphtheria may be communicable from animals to man. The duty that fell to Dr. KLEIN was to establish, if possible, the identity of the human and bovine disease. In this task, we think, as we have previously intimated, he was successful. The streptococcus which he detected in the sores on the udders of the affected Hendon cows, and by the inoculation of which he was enabled to reproduce in calves a fatal disease that resembled in its morbid anatomy the lesions of scarlet fever, supplied one link only in the chain of reasoning that led him to this important conclusion, and taken by itself could not, as Mr. CROOKSHANK points out, be held as direct evidence that the Hendon disease was identical with human scarlet fever. Dr. KLEIN was satisfied of the identity of the original streptococcus and that which occurred somewhat sparsely in the blood and tissues of the inoculated animals; and his known skill as an expert in these matters should go far towards ensuring acceptance of the accuracy of his statement. The real *crux* of the matter lies, however, in the later stages of his inquiry, which were communicated to the Royal Society and detailed at the Royal Institution. His examination of scarlatinal blood proved the difficulties of the inquiry, and is in remarkable contrast with the same examinations conducted by Dr. EDINGTON, who seems to have had but little trouble in obtaining from the blood in the early stages of the disease the bacillus which he holds to be characteristic of it, whilst at later periods there were found diplococci and streptococci, which appeared to replace the bacillus in the blood. There is, of course, considerable cogency in the argument that so scanty a growth of streptococci as Dr. KLEIN obtained from scarlatinal blood may have been due to accidental contamination, especially as no mention was made of any control experiments. But this view is outweighed by the further proofs adduced by Dr. KLEIN as to the identity in nature between the streptococcus of the Hendon cows, that found in the specimens of condensed milk connected with an outbreak of scarlatina, and that found in scarlatinal blood. It may be possible that the scarlet fever due to milk contamination is specifically distinct from other cases, but unless we are prepared to go so far we do not see any mode of escape from the conclusion to which Mr. POWER'S and Dr. KLEIN'S investigations have led them.

It is well, however, that so important a subject should be thoroughly viewed on all sides, and it is therefore a fortunate circumstance that Dr. EDINGTON'S researches should have been so far completed as to allow of their publication whilst attention was still being directed to the subject through Dr. KLEIN'S inquiry. More especially is this important, since Dr. EDINGTON proceeded on quite different lines, and devoted his main efforts to detect and isolate the specific contagium, of the existence of which in the desquamating epidermis there is little doubt. Dr. JAMIESON had succeeded in preventing the spread of scarlet fever by assiduous attention to disinfection such as bathing and antiseptic inunction directed to remove the desquamation as soon as it formed; and it was owing to this that he sought Professor KLEIN'S co-operation to have a thorough bacteriological investigation undertaken. The inquiry was placed in the hands of Dr. EDINGTON, who pursued it with great ardour, and his report contains a record of a large number of micro-organisms which he detected in the desquamation and in the blood, while [illegible] precaution against contamination. M[illegible] seem to have been innocuous, for wit[illegible] lations of animals produce any [illegible] was a bacillus, which occurred in [illegible] (an exception being in the case of a tu[illegible] before the organism had time to de[illegible]

Digitized by Google

the products of desquamation, and also in those obtained from the blood taken before the third day. Rabbits and guinea-pigs inoculated with this bacillus suffered from an erythema followed by desquamation; and of two inoculations made in the calf, one was fatal, and the lesions found after death were declared to be similar to those in man in the early stage of scarlet fever. There are, however, some weak points in the reasoning in favour of this being the scarlatinal germ, which have been pointed out in these columns by Mr. CROOKSHANK or "M.D." One is the close resemblance it bears to other non-pathogenic organisms that exist normally on the surface of the body. Then we have the curious association of this bacillus with other forms, most of which are indubitably little more than ectophytic parasites, and with one, which is not of this class (the diplococcus scarlatinæ sanguinis), the inter-relation is singularly close. That the bacillus should not be found in the blood after the third day, nor in the cuticle till after the end of the third week is, as "M.D." remarks, a singular feature in the life-history of such organisms. Lastly, there is a possibility of contamination here also, as in the case of Dr. KLEIN'S experiments.

Irreconcilable as these two series of researches are, they are both very suggestive, and point the way to further discovery. For whether the contagium of scarlet fever be a bacillus or a streptococcus, it has at any rate been demonstrated that it can be conveyed through milk, and transmitted thereby from the bovine to the human organism; and it has also been shown, as much by Dr. JAMIESON'S treatment as by Dr. EDINGTON'S bacteriological study, that it is contained within the desquamating cuticle, and that it may be directly attacked and rendered impotent by reason of this fact. It is, of course, impossible for the subject to rest here, on public as well as on scientific grounds. The grave question of the transmissibility of the disease from cattle to mankind is not to be dismissed with contempt like that in which the Agricultural Department of the Privy Council would seem to hold the results of Mr. POWER'S inquiry into the Hendon disease; nor, on the other side, can Dr. EDINGTON'S circumstantial and elaborate reports of his discovery be set aside without an attempt to verify or refute them. Bacteriology has achieved many successes hitherto, but as great a triumph as any remains for it if it can demonstrate without dispute the specific organism which few can doubt underlies one of the most contagious of human diseases. Mr. CROOKSHANK'S suggestion of a Commission is deserving of note, but hitherto we have not gained so much from bacteriological committees of inquiry as to make us sanguine of a satisfactory result.

IT is surprising that anyone interested commercially in the private asylum system should object to the Lunacy Bill introduced by the Government. Practically that measure creates a monopoly, and the proprietors of "licensed houses" existing at the date of the passing of the Act will be able to command their own prices for the establishments in their possession. Of course the legitimate and only rational way of settling the question would have been to buy out the owners or lessees of these houses. If the existence of asylums wherein lunatics are received and retained as a paying business is really opposed to the public welfare—in short, so opposed to it that Parliament deems it wise to prevent any extension of the commercial enterprise,—surely the system ought to have been at once abolished. Either there should be no limitation to the trade or it should be interdicted. Anything more monstrous, from an economic point of view, than the paltry and time-serving expedient which a spirit of parsimony and the influence of red-tape have combined to embody in this measure it would be difficult to conceive. This is the common-sense and only honest view of the matter. Meanwhile, as we have said, the proprietors of existing licensed houses have no cause to complain, and it is strange, indeed, that they should help to throw obstacles in the way of the passing of a measure so greatly to their advantage as the Bill now waiting the convenience of the House of Commons to be engrossed on the statute book. It is impossible to conceive that any obstinate opposition will be offered to its progress by those who have nothing to lose, but, on the contrary, much to gain when it shall become law.

There are doubtless some good features in the Government Bill: for example, that which—at least professedly—provides for the appeal of the alleged lunatic to an official and presumedly impartial judge; but even as regards this provision, meagre as it is, so much is left to "discretion" that we doubt whether anyone erroneously charged with being insane will be able to prove his sanity. If the Parliamentary Committee of the Medico-Psychological Association should have its way, the last vestige of hope in this direction will be dissipated. The committee would fain place the judge under the direction of the doctor signing the certificate. If this were done, the whole proceeding would be converted into a mere farce. Practically, the function of the lay judge or justice, as the Bill now stands, is to take the place of a guardian, and watch over the personal interests of the alleged lunatic, protecting him from *all* other persons as a parent should protect a child. When once the decision has been arrived at that the case is to be placed under treatment in an asylum, the doctor will be free to make his diagnosis and to carry out his treatment without interference. The generally admitted objection to the law of lunacy as it stands is that the preliminary question whether a man is or is not so ill as to necessitate his removal to an asylum is placed at the sole disposal of the doctor; and the mere fact of a decision that he is in need of such treatment puts an end to the liberty of the subject, and by a stroke of the pen destroys his claim to the right of self-control. This is held—and we think rightly so—to be a grave fault of the law. This Bill has for one of its objects to give the person thus placed an appeal to the decision of a lay judge before being removed to an asylum. If anything whatever is done to limit that appeal, or to embarrass the alleged lunatic in its use, for anything we can see the Bill will be waste paper, and ought to be abandoned. We have therefore no hesitation in expressing a hope that the committee of the Medico-Psychological Association will either withdraw its suggestion on this point, or that the Government will disregard it. Other objections urged—for example, that levelled against the judicious resolve that the medical practitioner who signs an urgency certificate shall not also sign the certificate on the subsequent petition—having for their purpose to baffle the endeavour to

Digitized by Google

free an alleged lunatic from the toils of any scheme laid for him, strike us as equally absurd and inexplicable.

Again, why should the endeavour to relieve medical practitioners from business which is in no sense professional be opposed? The treatment of mental disease is one of the very highest departments of scientific medicine; the trade in lunatic boarding and keeping is purely a business. Let there be no misapprehension as to what, precisely, we mean by these remarks. It cannot be supposed that we cherish any of the exploded theories about the inferiority of trade as a vocation. The man who employs his skill and acumen as a man of business in the keeping of boarding-houses for the insane is no less to be respected than the man who makes a profit by his skill as a scientist and practitioner of the art of healing, but the two vocations are no more compatible than would be the teaching and preaching of religion and the keeping of religious houses in which converts were to be retained at a profit. The labourer is always worthy of his hire, but he must not engage in two branches of industry the one of which plays—or may be made to play—into the hands of the other. It is a worthy enterprise to cure the insane, and it is a worthy enterprise to care for the insane; but inasmuch as the profits made by keeping asylums are capable of being increased by tardy treatment and slow cure, the two vocations are distinctly incompatible. Let us never forget the dictum of the founder of THE LANCET on this point: "If you say to a doctor, 'Sir, I will give you £300 a year so long as my liver is diseased,' what is the chance of having it cured?" It is useless to fly into a passion of virtuous indignation if we are suspected. We can only quite clear ourselves of suspicion by putting it out of the power of anyone to suspect us, therefore we protest that the profession of medicine ought to clear itself of the *possibility* of any suspicion with regard to the care and cure of the insane. The opposition to this really very meagre Bill fills us, we confess, with astonishment. We heartily hope it will pass: not because we think it effective; it is very far from securing thorough reform. Nevertheless, as the best we are likely to get, it is a duty to urge the Legislature very earnestly to pass the measure.

OF the several important papers contained in the volume of the Transactions of the Epidemiological Society which has just been issued, there is none which merits more serious attention than that presented by a Committee of the Society on the subject of vaccination. It is now many years since the Society put itself in communication with the profession, and collected evidence which was largely instrumental in bringing about legislation which has conferred untold benefits upon the kingdom. It was right, therefore, that after a lapse of years further inquiry should be made and a Committee appointed to report on the evidence which the present state of medical knowledge supplies as to the conditions affecting the protection afforded by vaccination against death by small-pox occurring in persons contracting that disease. This Committee, after seeking information from small-pox hospitals and from many practitioners, collected together the facts as to nearly ten thousand cases of this disease, and the results which are now published form the latest contribution to vaccination and small-pox statistics. Speaking generally these statistics fully substantiate the opinions previously held as to the protective value of vaccination, but when considered in detail they teach lessons which have not hitherto been fully understood. In previous papers on this subject it has been assumed that the appearances of vaccination marks are not altered as the result of time; the Committee, however, have been led to adopt a different view, and the grounds upon which their opinion is based appear to be sufficient to warrant the conclusion at which they have arrived.

When the death-rate from small-pox among unvaccinated persons is studied, it is found that there is a greater tendency to death when this disease attacks young children under five years of age than during the next quinquenniad; from ten to fifteen years the death-rate still further decreases, but after this period it increases again. For persons possessing foveated cicatrices, the result of vaccination in infancy, the lowest death-rate is during the first five years of life; but as the protective effect of vaccination wears out, the fatality increases in each successive age period. For persons, however, with unfoveated cicatrices at the time of attack by small-pox, the story is altogether different. After the first five years of life this kind of vaccination appears at first sight to become more largely protective than is to be accounted for by any lessening of mortality due to increased age, and the Committee explain this circumstance by attributing it to the disappearance of foveation in some persons whose scars previously possessed this character, leading to their inclusion with others who had never at any period had other than plain cicatrices, thus giving at a later age an apparent protective value to plain cicatrices which is greater than they deserve. This opinion is supported by the fact that when another class is considered, those who at the time of attack by small-pox have no vaccination scars, although they are stated to have been vaccinated, the same circumstance is observed; but the diminished fatality referred to does not occur until a later age period, leading to the conclusion that a longer period is required for the complete disappearance of a scar than for the loss of its foveation. This point is of so much interest that it deserves to be finally decided by direct observation of the changes in the appearance of vaccination scars in children; and those who have charge of the young, either in families or in schools, would do well to record any alterations observable after periods of time. The importance of foveation, and especially of permanent foveation, is emphasised; and certainly the kind of vaccination which produces scars of this character is that which should be aimed at.

In discussing the effect of quantity of scars, the evidence collected by the Committee shows the urgent necessity for the production of the larger number of vesicles, and it may be hoped that a perusal of the report will lead every vaccinator not to rest content with a smaller number of vesicles than that recommended by the Local Government Board.

The period of life at which revaccination should be performed must necessarily depend upon the character of the primary scars; but, under any circumstances, the

Digitized by Google

statistics show that even where vaccination has been well performed a greater interval than fifteen years should not be allowed to elapse between the primary and secondary operation. Indeed, we are reminded of the conclusion of the German Commission, of which an excellent account is given in the same volume, that the duration of the protection afforded by vaccination is on the average ten years.

The small-pox hospitals have supplied the Committee with the most positive evidence as to the immunity from small-pox conferred by revaccination upon attendants on the sick. Of 734 persons thus employed, 79 had previously had small-pox, leaving 655, of whom 10 were not revaccinated; all but these ten persons escaped small-pox, and all these ten were attacked. This should entirely dispose of the oft-repeated but erroneous statement of anti-vaccinationists that small-pox attendants escape disease from the fact that they are recruited from those who have already passed through an attack of small-pox. It is, indeed, impossible to read the evidence adduced on this point without understanding that it is within the power of every person absolutely to protect himself from all attacks of this disease.

Some of the difficulties of the Committee in obtaining information may well be taken to heart by those who have the control of small-pox hospitals. It is upon the evidence these institutions afford that we must mainly rely for teaching the public the value of JENNER'S discovery, and the want of a uniform system of recording statistics at once becomes apparent when any attempt is made to utilise them. The Statistical Committee of the Metropolitan Asylums Board will, it is to be hoped, in the future ensure that the records of their own institutions will be free from this objection; for others we must rely upon the interest which all medical men take in so important a means for preventing disease.

AN interesting contribution to the literature of the subject of the influence of infectious hospitals on houses in their neighbourhoods is contained in the last annual report on the health of the Hackney district. Dr. TRIPE, having convinced himself of the injurious influence which followed on the aggregation of small-pox patients in the Homerton Hospital, set himself to investigate the effects following the use of that hospital for the purpose of isolating cases of scarlet fever. In dealing with this disease in a district where compulsory notification is not in operation, greater difficulty is met with than is the case as regards small-pox, and this because the cases of the former disease reported to the health officer are not so numerous as in respect of the latter class of disease. But doing the best with the materials which were available, Dr. TRIPE marked out the district around the hospital in circles having quarter-mile, half-mile, three-quarter mile, and one mile radii, in the same way as had been done with small-pox, and during 1886 he obtained the following results. In the quarter-mile area 44 out of 283 houses were invaded; that is to say, 15·5 per cent. of the cases occurred there against 6·1 per cent. of houses in the whole district. Between the quarter-mile and half-mile radii there were 112 houses invaded, or 39·6 per cent. amongst 15 per cent. of the total number of houses. Between the half-mile and three-quarter-mile radii there were 35, and between the three-quarter-mile and one-mile radii 31 houses invaded, making a total of 23·4 per cent. of cases amongst 31·5 per cent. of the total houses, and outside the one-mile radius 61 houses were invaded, or 21·5 per cent. of all infected amongst 47·4 per cent. of the total number of houses.

These figures might be regarded as indicating some injurious influence of the hospital on the population, but a glance at the map which illustrates the report goes to show that any such influence could not have been aerial, as in the case of small-pox, but that it might have been induced by personal contact, as during traffic, the disease existing chiefly in the streets which form approaches to the hospital. And not only so, but the disease attacked one group and spared another in the same area, and this although the inhabitants of the area having immunity were poor, and were certainly not in the enjoyment of sanitary arrangements of a better sort than were their neighbours in localities infected. Then, again, there is an absence of that constancy which marked the influence of small-pox hospitals. The returns for scarlet fever in 1882, being submitted to a similar examination, are quite different from those for 1886, and they would point much less conclusively to any mischievous effect. Having regard to the total result of the inquiry set on foot, Dr. TRIPE gives his opinion to the effect that his statistics as to scarlet fever "show that it is not at all likely to spread from a hospital in the way that small-pox has done, and that, whilst it is almost certain that hospitals for small-pox in London have proved injurious, those for scarlet fever tend to reduce the spread of that disease."

We should hardly have gone so far as to draw this conclusion from the facts to which this report is limited; but we find that it is at least in accord with previous experience in this respect. When Dr. THORNE THORNE published his official report on the influence of hospitals for infectious diseases, he, with the aid of Mr. SHIRLEY MURPHY, then resident medical officer to the London Fever Hospital, set out in a tabular and diagrammatic form the history of houses surrounding that hospital with regard to scarlet fever and to several other infectious fevers. The result was that over a series of years the number of attacks from scarlet fever in houses immediately surrounding the hospital happened to be slightly less than that which might have been expected to have occurred in a similar group of houses situated elsewhere than near an infectious hospital. Very similar experience was obtained at Sunderland and Warrington, where the infectious hospitals were situated in close proximity to the houses of the labouring classes. As yet the investigations into this subject have not been of the precise character that have marked the similar ones as to small-pox hospitals, and hence we think it wise not to draw any very definite deductions from them; but we can at least assert that, apart from spread of disease under conditions of personal contact, which should not be allowed in a properly administered hospital, scarlet fever hospitals have never been shown to have any but a beneficial effect on the communities providing them.

IT is understood that the Medical Council will appeal from the decision of the Court of Queen's Bench in the case

Digitized by Google

of Reg. *versus* the General Medical Council. The case, our readers will remember, was an application on behalf of Mr. H. F. PARTRIDGE for a *mandamus* ordering the Medical Council to restore his name to the Register of Dentists, from which it had been removed under the Dentists Act, 1878. The name was erased in the following circumstances. Mr. PARTRIDGE, though entitled to be registered under the Dentists Act in virtue of being in practice before it was passed, elected to be registered in virtue of a diploma in Dentistry which he held from the Royal College of Surgeons of Ireland, subject to the condition that he should not seek to attract business by advertising or by any practice considered by the College to be unbecoming. In 1883 the Royal College of Surgeons of Ireland withdrew or cancelled his diploma on the ground that Mr. PARTRIDGE had attracted business by advertising. Mr. PARTRIDGE'S diploma being withdrawn, his *locus standi* in the Register seemed to cease; and accordingly the Medical Council in February, without any independent examination of the case, ordered the Registrar to erase his name from the Register. The Dentists Act differs in an important respect from the Medical Act. It does not contain a clause like Clause 28 of the Medical Act, which provides that Colleges or bodies exercising the power of striking off the names of any of their Members shall signify the same to the General Council; and that the Council may, *if they see fit*, direct the Registrar to erase from the Register the qualification derived from the College or body in respect of which such member was registered, always provided that the name of no person shall be erased on the ground of his adopting any particular theory of medicine or surgery. This provision is not repeated in the Dentists Act; and Mr. FINLAY, Q.C., with much skill, argued that it must have been present to the framers of the later Act, and been by them intentionally omitted. From this position he went further, and argued that it was clearly not the intention of the Act to give the Medical Council power to erase except under Clause 13. The Court of Queen's Bench endorsed this view, and laid down that the Council are not entitled to remove a dentist's name from the Register, even under Section 13, merely on the report of any College or body that it had removed a given name from its list of members, except after an independent inquiry and proof that the person affected had been guilty of certain offences specified in the clause—viz., of infamous or disgraceful conduct in a professional respect.

This decision may be a very sound one in point of law, but it leads to some curious consequences. The Council is required to publish from time to time a *correct* copy of the Dentists' Register. Obviously a Register is nothing if it is not correct. Is it possible for even the Queen's Bench to require the Council to publish a Register that is incorrect? Clearly we think not. How, then, can the Court order the Council to register the possession of a qualification which has been cancelled? It may be said that Mr. PARTRIDGE was entitled to be registered in virtue of being in practice before 1878. So he was, but this title to registration lapsed after the first day of August, 1879. The consideration of such lapsed right to registration might advantageously have been remembered by the Council when

It is difficult to see in what sense Mr. PARTRIDGE can be registered under this decision. His name may be inserted, it is true; but what is a name in a Medical or Dental Register without the facts or letters which indicate the nature of the right to be there? The advantage of such a registration would be very doubtful. It could not excite anything but inquiry, and such inquiry would elicit the fact that the only qualification once possessed had been withdrawn. The case is one of the many which go to prove that the Medical Acts are drawn with culpable carelessness, and are more calculated to benefit the legal than the medical profession or the public. We shall be curious to see if the Court of Appeal will confirm a judgment which leaves both the Council and the suitor in such an unsatisfactory position, to say nothing of its tendency to encourage modes of attracting "business" which we can only regard as derogatory to the dental profession and as militating against the interests of the public.

Annotations.

"Ne quid nimis."

THE VACANCIES IN THE COUNCIL OF THE COLLEGE OF SURGEONS.

ON former occasions we have sought to influence the prospective action of the Fellows in their voting with a view to secure such new members for the Council as would be most suitable for the attainment of those changes in the policy of the College that are so much sought for by the profession at large. On this occasion matters are quite changed, and nothing that we can now say will have any influence on the immediate action or policy of the Council, directly or indirectly, seeing that the Council, for good or for evil, and notwithstanding the recent introduction among them of men more or less pledged to reform, have rejected all overtures made to them by their constituents. For the Council have now presented their petition for a new Charter, which, while embracing considerable changes, some directly opposed to the wishes of the Fellows and Members, completely ignores the three great desiderata as formulated at the annual meetings of the College and carried by overwhelming majorities. Nevertheless, it is desirable that all those who really wish to see the Council reformed should sustain their efforts, and should vote only for such candidates for seats as will be likely to keep up and [illegible] the reform element which already exists, though [illegible] a minority at present. A few weeks ago we published a brief abstract of the changes sought by this Council. At the risk of seeming wearisome, we may remind our readers that these changes leave untouched the three [illegible] proposals made at and passed by the annual meetings, viz., (1) that the Council shall present a report [illegible] reprint of the Minutes of their proceedings) for discussion by the annual meeting; (2) [illegible] tion in the Constitution, or in the [illegible] College, or in any of its bye-laws or [illegible] effected without the consent of the Fellows [illegible] convened to discuss the same; and (3) [illegible] Members, under certain restrictions, [illegible] shall take part in the election of, and [illegible] Council. These fundamental changes in the [illegible] of the College have been [illegible] resolved to agree to [illegible] by the Council [illegible]

Digitized by Google

with a *non possumus*, and are now seeking for what will practically amount to the endorsement of this policy by the Privy Council. It remains to be seen with what success. The two Associations of Fellows and Members respectively have done, and we hope are still doing, their utmost to have their views represented in any new Charter that may be granted. It will indeed be strange in these days of general representation if the wishes of a large body of the Fellows and the petition of some six thousand carefully educated Members of the College of Surgeons be entirely ignored in matters of such obvious common sense as those in dispute. Besides the three great questions just alluded to, there are continually cropping up questions in which the general practitioner is largely and chiefly concerned, and in legislating on which it is quite clear that his practical knowledge will prove of real service.

THE CONJOINT COLLEGES.

THE following report on the utilisation of the vacant ground adjoining the Examination Hall on the Thames Embankment will be laid before the respective authorities of the two Colleges at early meetings:—"1. That a central theatre for lectures and demonstrations should constitute a part of the proposed additional buildings. 2. That the central theatre should be built so as to contain seats for an audience of about 250 persons. 3. That the plan submitted by the architect be, in its general arrangements, adopted, and recommended to the two Colleges, it being understood that the theatre shall be constructed to contain about 250 persons, and that the side wings be proportionately enlarged. 4. That, subject to the approval of the above resolutions by the two Colleges, a subcommittee be appointed to investigate and report upon the best arrangements at present existing in scientific institutions in the construction of a lecture theatre and laboratories. 5. That the appointment of the subcommittee be left in the hands of the two Presidents of the Colleges, and that the subcommittee be requested to report within four months."

POLICE AMBULANCE ARRANGEMENTS ON JUBILEE DAY.

THE ambulances consisted of six horse-ambulances and various bearer sections. The horse-ambulances were posted as follows:—One in Scotland-yard, one in Dean's-yard, one at King-street Police-station, one at Buckingham Palace, one in Cleveland-row (at the bottom of St. James's-street), and one at the entrance to Spring-gardens, opposite the Union Club. The bearer sections occupied positions at Scotland-yard, Parliament-square, the Abbey, King-street Police-station, Hyde-park-corner, top of St. James's-place, bottom of St. James's-place, Piccadilly-circus, Waterloo-place, Spring-gardens, Charing-cross, and the Embankment end of Northumberland-avenue. Three of the horse-ambulances, fully equipped and with an efficient *personnel*, were kindly placed at the disposal of the police authorities by Mr. John Furley of the St. John Ambulance Association, whose name has been so long and honourably before the public in connexion with ambulance work both in civil and military practice. Mr. Furley personally superintended the working of his ambulances, and Mr. S. Osborn, as the surgical representative of the Order of St. John, was in charge of the horse-ambulance in Dean's-yard. The permission of the General commanding the Home District having been obtained, the Volunteer Medical Staff Corps, under the command of Surgeon-Major Norton, furnished three strong detachments, consisting of about 160 men. The police ambulances provided eight bearer sections, the men being specially selected for this duty from those who had previously served in the Army Hospital Corps (many of them wearing the medals of two or three campaigns), and from those who had obtained certificates of proficiency and efficiency in ambulance duties. The equipment, stretchers, haversacks, and water-bottles were kindly supplied by Surgeon Lees Hall, A.M.D. (adjutant of the Volunteer Medical Staff Corps), whose services were extremely valuable. The various ambulance contingents paraded at Scotland-yard at 8 A.M. on the morning of Tuesday, when after a few words of address from Sir Charles Warren, they marched off to their allotted positions. Medical men were posted in various parts of the Abbey. Dr. H. G. W. Mackenzie and Mr. Battle of St. Thomas's Hospital were in the Triforium, Dr. Hawkins in the Peers' Gallery, Mr. Farr at the north door, Dr. Marsden Low at Poets' Corner, and the Chief Surgeon of the Metropolitan Police at the Royal entrance. Fortunately, their services were not called into requisition. The accidents and casualties treated by the ambulances were rather numerous than serious, and consisted mainly of individuals fainting and crushed by struggling in the crowd, fits, contusions, wounds, and injuries and fractures of limbs. At Piccadilly-circus so numerous at one period were these minor casualties that Dr. Kemp, the divisional surgeon in charge, felt himself compelled to utilise the Vine-street Police-station as a temporary hospital. All the details are not to hand, but it is roughly computed that between 500 and 600 were treated in the streets. The serious cases, fortunately few in number, include a fracture of skull, admitted into St. George's Hospital; concussion of brain and severe injuries of chest, resulting from a kick from a trooper's horse, which shortly proved fatal. Dr. A. E. Hardy, house-surgeon to Charing-cross Hospital, has kindly sent us the following list of cases treated at that hospital on the 21st. Contusion 1, sprains 6, various wounds (slight) 31; fractures, of the radius 2, forearm 1, leg 1; dislocation of shoulder 1, alcoholism 5, syncope 2, hysteria 1, epilepsy 7, sunstroke 2, brought in dead 1, trivial cases 11. Ten cases were admitted: severe contusions 3, concussions 3, epilepsy 2, apoplexy 1, delirium tremens 1. Altogether about 98 cases required attention. This is a fair example of the kind of cases treated during the day chiefly at the hospitals along the line of route—viz., Charing-cross, St. George's, and Westminster. Every assistance was given by the police, and the numerous cases were rapidly transported to the hospitals or to their homes. The arrangements, which were, we believe, made but a few days before, were admirably carried out, and Sir Charles Warren, the Commissioner of Police, and Mr. MacKellar, F.R.C.S., Chief Surgeon, are entitled to the highest credit.

HYDROSTATIC PRESSURE IN INVERSION OF THE UTERUS.

PROFESSOR MAX RUNGE of Dorpat, having a case of inversion of the uterus, caused by a midwife pulling on the cord which had been allowed to remain without medical advice for nine weeks, made several fruitless endeavours to effect reduction by manipulation and by distension of the vagina, by means of Braun's colpeurynter, which consists merely of an indiarubber ball with thin walls, provided, like Barnes's bags, with a tube and stopcock. He then bethought himself of a plan recommended and practised successfully by Krukenberg—viz., the application of considerable hydrostatic pressure to the vaginal canal, with the view of dilating the os uteri and of softening the inverted uterus itself. Professor Max Runge sprinkled the colpeurynter well with iodoform, and again introduced it, connecting it with a vessel of water hung at the height of about 3 ft. 8 in. above the bed. Communication between the colpeurynter and the water-vessel was kept open, the stopcock not being turned off, and so a high degree of hydrostatic pressure was continually exerted, distending the vagina

Digitized by Google

and the os and compressing the body of the uterus. Next morning the pain caused by the apparatus became unendurable, and the patient pulled it away from her. Upon examination, it was found that the fundus had retreated within the os, which was widely distended; there was still, however, a partial inversion, which was readily reduced with the finger. The uterine cavity was then washed out with a carbolic solution, and a tampon of iodoform wool introduced into it. The mucous membrane of the vagina showing signs of sloughing, it was well powdered with iodoform; ergot was also given. The parts were carefully dressed for some days, and the patient made a rapid recovery.

DEGREES IN MEDICINE AND SURGERY FOR LONDON MEDICAL STUDENTS.

AN extraordinary meeting of the Fellows of the Royal College of Physicians has been summoned for Monday next, at which a report from the delegates of the two Colleges on the granting of degrees in Medicine and Surgery will be submitted for approval. The chief features in the report are the refusal to undertake united action with University and King's Colleges in the formation of a new University to confer degrees in Arts, Science, and Medicine, and the recommendation of an application for a charter and power to grant degrees in Medicine and Surgery by the two Colleges acting jointly, but independently of any other bodies. We understand that the charter will suggest a governing body of forty-eight persons (twenty-four from each College), and that power will also be sought to confer degrees on those who have already passed the examinations for the membership of the College of Surgeons and for the licentiateship of the College of Physicians.

CONTAMINATION OF THE THAMES BY THE HENLEY REGATTA.

WHEN last year we published a special report on the contamination of the Thames at the Henley regatta, the matter was brought before the House of Commons. To a question put by Mr. H. S. Wright, the President of the Local Government replied that the Thames Conservators, acting according to the Act passed in 1885, had drawn up bye-laws which would enable the owners of house boats to be prosecuted if the drainage of these vessels went into the Thames. The bye-laws only awaited the approval of Her Majesty in Council. With this assurance the public was lulled into a sense, we regret to say, of false security. On inquiry we find that even at this, the eleventh hour, the bye-laws in question have not yet received the Royal assent. The Henley regatta will be held on June 29th, 30th, and July 1st, and the owners of house boats, steam launches, and other craft are still at liberty to drain their sewage into the chief drinking-water supply of London. This scandalous state of affairs seemed so inexplicable that we at once proceeded to inquire at the Thames Conservancy office as to what were the causes of such a dangerous delay. We were then informed that immediately after the publication of our report on the contamination of the Thames at the Henley regatta, the Thames Conservancy drew up a set of bye-laws calculated to put an end to the grievance. These, according to the law in such matters, were extensively advertised and objections invited. Such objections were entered, but they did not relate to the clauses protecting the Thames from contamination. It was the rules concerning the marking and numbering of the boats which elicited the opposition of many of the persons concerned. Nevertheless, the delay was effective in retarding the whole measure. The bye-laws had to be drawn up again in a modified form and once more advertised. A few objections were raised to this second project, but we have good reason to believe they were not of a serious nature, so that there is now no valid reason for withholding the Royal assent. This may be obtained at any moment—perhaps, we were informed, in three days, or in three weeks, or in three months. We would earnestly urge that there is not an hour to be lost. The Thames Conservators, with commendable energy, have drawn up and printed a circular, which they will send to the owners of every house boat the moment the Royal sanction to the new bye-laws is given. This circular points out that by Clause 9 of the new Regulations in question, a penalty will be inflicted on those who "cast or throw into or upon, or place or cause or suffer to fall or flow into or upon any of the places specified in Subdivision 1 of this bye-law, any sewage, rubbish, or other offensive matter or thing." But till this bye-law is approved, custom, long established, allows the drainage of boats into the water on which they float. Rubbish, sand, and ballast may not be thrown into the river. This is forbidden by the 27th and 28th Victoria. And the 29th and 30th Victoria prevents the drainage of houses into the Thames; but the Thames Conservators do not consider that these Acts empower them to interfere with the construction of watercloseta on board vessels, even if these navigate the Thames above the intake for the drinking-water of London. On the other hand, foreseeing that the Royal assent will probably not be obtained in time to prevent the mischief and danger caused by the large concourse of crafts at Henley during the regatta week, the Thames Conservators, at their own cost, have followed our suggestion and appointed two scavenging barges. These will pass up and down the course both morning and evening, so as to remove the contents of night-stools and all the garbage and refuse. It is to be hoped that the visitors will profit by this new facility placed at their disposal, and will not throw overboard anything likely to befoul the water. Nevertheless the bye-laws should have received the necessary sanction before this, and so important a matter ought not to have been left to mere voluntary effort. It is hardly yet too late; and we still hope to see this error of neglect rectified before the Henley regatta week.

INCREASE OF ALCOHOLISM IN FRANCE.

A SPECIAL commission appointed by the French Senate to investigate the above-named subject has drawn up a regular impeachment against the trade in alcohol. During the last ten years the consumption of alcohol in France has increased from 970,000 to 1,500,000 hectolitres. This, however, only represents the officially recognised figure; the fraudulent and clandestine trade in alcohol cannot be estimated, though it is considerable in amount, and the liquor thus vended must be vile in quality. The number of suicides attributed to excessive consumption of alcohol has multiplied sixfold during the ten years in question—1874 to 1885. There were formerly 137 cases per annum; there are now 868. In those departments there has been a notable augmentation in the sale of alcohol, the number of recruits who have proved unfit for military service has increased fourfold. Criminal assaults have also largely multiplied in these same counties. The proportion of patients suffering from insanity due to alcohol received in public asylums has, on an average, risen from 9 to 16 per cent. during the last ten years. In certain departments, out of the total number of insane from alcohol the proportion given of those who are victims of alcohol reaches the enormous figure of 21, and even, in one case, 28 per cent. During the last five years (1881-1885) there have been 51,000 insane received in the public asylums, and of these no less than 7400 cases are said to have been due to the excessive use of alcohol. Among the accidents recorded, no less than 20 per cent. are attributed to drunkenness; and the birth-rate has also notably decreased in those parts of the country where the use of alcohol has

Digitized by Google

increased. Yet all these are but official figures, and the case would be even worse if it were possible to record all the facts that escape the control of the public authorities. Nevertheless, the indictment is strong enough as it stands, and the Commission of the Senate have not failed to express their serious alarm and concern. To remedy the evil, it is proposed to increase the tax on alcohol, and to impose more stringent regulations with respect to wine shops. This, however, will scarcely meet the case. The phylloxera is undoubtedly in a great measure responsible for the increase of drunkenness in France. Given cheap and pure wine, there would probably be but little alcoholism. Drunkenness is almost unknown in wine-growing countries; and intemperance in France prevails principally in the northern departments, where the vine cannot grow. What is more particularly wanted is the stringent application of laws against the sale of bad alcoholics and adulterated wine, combined with facilities of transit, so that pure wine may be brought within reach of the poorer classes. When once the palate is accustomed to natural and wholesome wines, the intoxicants that do so much harm will be considered too coarse to be drunk with any sort of pleasure. A Spanish peasant from the vineyards of Andalusia, accustomed to the unsophisticated Manzanilla or the Montilla of his native country would find the schiedam drunk in Northern Europe inexpressibly nasty. It is difficult to prevent drinking by Act of Parliament, but the Legislature may seek to check fraud and adulteration.

A CURIOUS VERDICT.

AN inquest was held at the Crowndale Hall, Crowndale-road, on June 15th, by Dr. Wynn Westcott, deputy coroner for Central Middlesex, touching the death of a man aged fifty years. Deceased had been in pecuniary difficulties, and on one occasion, some three months ago, he stated that had he not been relieved he would have poisoned himself with the contents of a packet he produced from his pocket. About a fortnight before his death he disappeared from his home and was not heard of for a week, nor was his whereabouts subsequently traced. When he returned home on June 7th he appeared very ill, and was suffering from symptoms of gastric irritation. During the week he confessed to his wife that he had taken poison, and directed his son to the contents of his coat pocket. Two packets, each of which had been opened, were there found. They bore labels marked "Oxalic acid," "Poison." One packet was nearly empty, and a small quantity of the acid had been taken from the second packet. The chemist who supplied the acid deposed that each packet originally contained half an ounce, but that he had no knowledge of the purchaser, as the poisons falling under Schedule B of the Sale of Poisons Act, it was not necessary that it should be signed for. Dr. Mac Larty, of 204, Camden-road, was called to deceased on June 9th, whom he found suffering from vomiting, pain in the stomach, and other symptoms of gastric irritation. Medicines were prescribed for the alleviation of the patient's troubles, but death from exhaustion ensued on June 11th, two days later. Although the wife of deceased knew that her husband had admitted taking poison, she did not tell Dr. Mac Larty of the circumstance; consequently, in the absence of other evidence, there was no indication for other than symptomatic treatment. Very promptly, but unfortunately, an alkali was administered; just the last drug one would think of giving in a case of oxalic acid poisoning, on account of the solubility of the sodic and potassic oxalates, compounds practically as poisonous as oxalic acid itself. There was no evidence, however, to show that any acid had been taken after deceased returned home—that is, within three days of Dr. Mac Larty seeing him. The necropsy was conducted by Mr. Pepper on June 14th, the day before the inquest. The stomach was found to be acutely inflamed, the whole surface presenting a bright-red appearance, varied by black arborescent markings due to coagulated blood in the veins of the submucosa. There was no corrosion. The lower half of the œsophagus was affected in much the same manner as the stomach, and there was slight corrugation of the mucous membrane at the cardiac end. The mucous membrane of the small intestine was much congested. In reply to the coroner, Mr. Pepper said he had no doubt that an irritant poison had been taken, and that analysis showed this was not metallic, nor was it a mineral acid or caustic alkali. The condition of the stomach might possibly have been caused by a large quantity of strong alcohol, but it was more consistent with poisoning by oxalic acid. He doubted if oxalic acid would be found in the stomach five days after it was exhibited, as it was soluble, and would be farther got rid of by vomiting and diarrhœa. The lungs were extremely congested, but there was no hepatisation. There was nothing abnormal about the brain. The viscera generally showed signs of degeneration incidental to age, but were not so diseased but that life might have been considerably prolonged under ordinary conditions. Dr. Westcott advised the jury that a further analysis would probably disclose nothing more of importance, and that it did not seem necessary to adjourn the inquiry. The jury, after consultation, returned a verdict of "Death from natural causes, accelerated by alcohol," whereupon the coroner pointed out that the medical evidence went to show that the stomach had been acted on by some irritant poison, and that there was an entire absence of recent alcoholism. At his suggestion the verdict as registered ran, "Death from syncope, consequent on inflammation of the stomach and gullet, but that how the latter was caused there was no direct evidence to show."

THE PATHOLOGY OF FATIGUE.

PROFESSOR ANGELO MOSSO of Turin, with the aid of coadjutors in his laboratory, has for some years been working at the physiology of fatigue, and now he has turned his attention to the pathological manifestations of that physical condition. Fatigue carried beyond the moderate stage, at which it is decidedly beneficial, subjects the blood to a decomposing process through the infiltration into it of substances which act as poisons—substances which, when injected into the circulation of healthy animals, induce malaise and all the signs of excessive exhaustion. The researches which seem to justify this finding are embodied in an elaborate paper recently submitted to the Accademia dei Lincei, and shortly to be made accessible in its printed Transactions. Fatigue, according to Prof. Mosso, when incurred within limits regulated by the resisting power of the subject, has its pleasures and even joys—these being the expression of the organic consciousness that the active destruction of tissue is normally balanced by its reconstruction, a process yielding the sense of reinforcement and exhilaration. It was on the soldiers of the Italian army that Mosso's experiments were made, and he has convinced himself that he has arrived at practical regulations as to the amount of exertion to be put forth on the march, as to the best distribution of the halts and of sleep, and as to the lightening of the weight each soldier has to carry. The tent, for instance, which the Italian linesman has to take in his knapsack might, he thinks, be advantageously dispensed with. Again, the *vexata quæstio* of the comparative strength of the much-extolled Roman legionary and his modern counterpart has not been neglected by Professor Mosso, who has even traversed the archæological field in order to settle it. He has examined the richly-furnished museums of antique Roman armour and *impedimenta* scattered through the Italian cities, and he comes to the conclusion that in point of stature and bodily power the modern soldier is in no way inferior to the ancient. The Roman armies under the ablest

Digitized by Google

disciplinarians had their stragglers and their physically distressed upon the march; while the treatment available for their wounded on the battlefield and the ambulance-tent was comparatively rude and ineffective. And yet they were the conquerors of the then known world.

MORTALITY IN MANCHESTER.

THE high death-rate that has prevailed in Manchester in recent years, and the still higher rate that has been recorded there since the beginning of this year, seem to call for more local attention than has yet been given to the matter. The recorded death-rate in this city appears, from the Registrar-General's returns, to have averaged 26·5 per 1000 in the five years 1881-5; it was 26·3 during 1886, and in the first twenty-four weeks of this year the annual rate has been equal to 30·7 per 1000. Now the mean death-rate in the twenty-eight largest English towns during the five years 1881-85 did not exceed 21·5 per 1000, and was 20·9 in 1886; in the first twenty-four weeks of this year the mean annual death-rate in these towns was 21·2. These figures show a striking excess in the Manchester death-rate compared with the mean rate in the twenty-eight towns, an excess which has prevailed continuously during the past six years, and has been more strongly marked since the beginning of this year. In each of the last six years Manchester has been placed last, or last but one, in the list of these towns ranged in the order of their rates of mortality from the lowest. If the recorded death-rates in these twenty-eight large towns be corrected for differences of age and sex distribution, as is done by the Registrar-General in his annual summary, the result shows that the recorded and uncorrected death-rate in Manchester considerably understates the excess of mortality in the city. The age and sex proportion of Manchester is so exceptionally favourable to its mortality that the recorded death-rate in 1886 (26·3 per 1000) is raised by the Registrar-General's method of correction to 29·4 before it is fairly comparable with the corrected rates in the other large towns, and the general rate in England and Wales. The corrected rates in these twenty-eight large towns last year ranged from 17·6 in Brighton, 18·9 in Derby, 19·5 in Hull, and 20·0 in Bristol, to 26·1 in Liverpool, 27·8 in Blackburn, 29·4 in Manchester, and 31·4 in Preston. All the four towns at the bottom of the list are Lancashire towns, to which may be added Bolton and Oldham, which stand next to them, with rates very little lower than the rate in Liverpool. The Manchester sanitary authority has, we believe, asserted that the Registrar-General under-estimates the present population of the city, and thus overstates its death-rate. So far as we know, however, no serious attempt has been made to prove the probability of this assertion, by furnishing returns of inhabited houses on the rate-books of the city. The numbers of births annually registered in the city since 1881, moreover, do not afford evidence of increase of population since the last census much exceeding the small rate that prevailed within the present boundaries of the city between 1871 and 1881. We do not propose on the present occasion to discuss the causes of the long-continued high death-rate in Manchester. It should, however, be noted with reference to the death-rate in 1886, which was almost identical with the rates in 1884 and 1885, (1) that the mortality from the principal zymotic diseases was considerably above the mean rate in the twenty-eight towns, and that the excess was especially marked in the mortality from scarlet fever and "fever," which in most other towns shows a striking reduction resulting from improved sanitary organisation; and (2) that the excess of mortality is conspicuous at all ages, infant mortality being 183 in Manchester, against 169 in the twenty-eight towns, the death-rate among children and adults between one and sixty years was 16·0, instead of 11·8, in the aggregate population of the large towns, and the rate among persons over sixty years of age was 101·4 per 1000 living at those ages, against a mean rate of 77·1. Such facts as these should engage the serious consideration of the sanitary authority and of the ratepayers of the city of Manchester.

MERCURIAL INJECTIONS.

A DISCUSSION has recently been taking place in the Brussels Medical and Scientific Society as to the relative advantages of mercurial injections and inunctions combined with internal medication. Dr. Thiry prefers the latter method, as he thinks injections are attended with serious risks and inconveniences. M. Ed. de Smeth, on the other hand, practises injections largely—in fact, always—when mercury is indicated in syphilitic patients. At present there are in his wards 24 such cases in which no less than 900 injections have been given without any accident occurring; and M. de Smeth thinks that, as, apart from his own practice, M. Martineau has reported a series of 180,000 injections without any accident, Lewin 300,000 with 20 abscesses, and Paikert 5000 without any, it cannot be said that this form of treatment is more liable to inconveniences than other forms. He points out that there is a great difference between injecting insoluble salts, as calomel and the yellow oxide, in the way recommended by Scarienzo, upon which method M. Thiry's experience of injections was mainly gained, and injecting soluble salts, which is the plan he himself prefers and follows. Here, he says, the only objection to the injections is that the patient must be regularly seen by the doctor, which in private practice is sometimes inconvenient. Of course care must be taken that the syringe is perfectly clean and that the liquid is well filtered. In order to illustrate the occasional importance of the rapid action which can only be obtained by the method of injecting soluble salts of mercury, M. de Smeth mentions a case of syphilitic laryngitis of so urgent a character that it was thought that laryngotomy would be needed. However, by means of hypodermic injections repeated five or six times during the course of twenty-four hours all danger was averted.

CORSETS AND TIGHT-LACING.

IT has always seemed to us to be somewhat of a satire on the work of nature that the female form should be thought to require the support of a corset in order to make it graceful. We observe therefore with satisfaction that ladies, and even young ladies, are here and there to be found who have with equal courage and good sense dispensed with this unnecessary article of dress. Among the majority who continue to wear it there are also signs, though less pronounced, of the same healthy tendency. Tight-lacing is viewed with much less favour than formerly. Women as well as men are coming to see that artificial slenderness is no beauty, and indeed the sham and unreason apparent in a figure wantonly contracted must create in all thinking persons a feeling of repugnance which effectually prevents the possibility of admiration. Victims of this hurtful practice and grievous error in taste are still, however, not uncommon. Only a few days ago an inquest on the body of an elderly female revealed the fact that death was due to the direct consequences of her having the stays too tightly laced. This is by no means the first instance in which the coveted fineness of waist has been thus dearly purchased. It is, in fact, impossible that this custom can but injure health, for what are its effects? By tight-lacing, which forces together the elastic ribs and narrows the space within the thorax, free action of the lungs is obviously rendered impossible, the liver and heart are displaced, and the great bloodvessels unnaturally stretched. The organs placed at a

Digitized by Google

ower level are hardly less affected, and the pressure tells nore or less on every important structure between the ollar-bone above and the pelvis below. The unfortunate vorshipper of a false ideal thus loses with free respiration he due effect of the most powerful force which aids the eart in driving its blood through the body—the force of horacic suction. Displacement of the heart, moreover, an only result in palpitation, or severer cardiac troubles. Thus it comes to pass that every organ and tissue is under-ourished, digestion is little more than a meaningless term, nd healthy life in any part of the body is unknown. This ıay seem to be forcible language, but it is nevertheless the :lothing of facts which it does not merely envelope, but in ıany cases fits with a strictness not incomparable to the rm embrace of the most fashionably strait corset.

THE VETERINARY PROFESSION AND PUBLIC HEALTH.

A WELL-KNOWN veterinary surgeon has, in a letter to *he Times*, protested against certain recent statements ılculated to reflect on the attitude of the veterinary pro-ession towards the scientific study of animal diseases hich are related to the health of man. We are convinced ıat it would be unfair to attack the whole profession because ırtain of its members have recently appeared less willing to ılue scientific observation than we think should have been ıe case. As matter of fact, however, diseases of the lower ıimals have hitherto been considered rather in relation to eir effect upon these animals than to the health of man. or this no possible blame can attach to veterinarians; it ıs been necessary in the first instance for the importance these maladies to be recognised; but we are sure, now that me have assumed unexpected prominence, they will meet ith all the consideration they deserve. The scientific study disease, whether of man or of the lower animals, has come more possible during the last few years owing to e better opportunities which exist for its investigation, d a more definite knowledge is now expected than here-fore. No public health department is complete without e aid of those skilled in animal diseases, and we anticipate e need for services of this kind will not less stimulate the ıuiries of veterinary surgeons than it has members of our n profession. It is not many years ago that human infec-us diseases were not properly differentiated; it will pro-bly not be long before those of animals are as well under-od as are now human maladies of this kind. With the ssibilities of experimental inquiry which are open to the erinary profession, it may, indeed, be expected that the owledge of animal diseases will soon be more precise ın that of human maladies.

DAIRY SCHOOLS.

THE future of dairy farming in this country is a subject ıssessed of no small interest for the whole population. e importance of fat in food, alike as a sustainer of mus-ar energy and of the body heat, is now better understood n formerly. The daily and universal need of milk, the lculty in many quarters of obtaining it unadulterated, well-founded accusations levelled at it of late years as a rier of disease, not to mention many other matters ıting to the quality and cost of dairy produce in general, st therefore commend themselves to us as cogent reasons y education should have more to do than it has had h teaching the best methods of conducting this great ıstry. We hear on all hands complaints of foreign com-ition, and it is not remarkable, nor on the whole to regretted, that other nations compete with us in this artment of trade. The public is better fed in con-ience. It is not certainly any measure of protection we would ask for in the interest of home producers; but nothing can be more reasonable than the proposal that dairy schools should be established in conjunction with dairy factories in various rural districts. This would strengthen the competition on our side, and would go far to ensure a general supply of sound produce and the correction of existing abuses. A suggestion has been made that such a scheme should be instituted with the help of a moderate Government grant. It would certainly be better, however, if the project could be worked without applying to the national exchequer; and it seems to us that farmers, by combining for this purpose, especially when assisted, as they must be, by the proceeds of the factories, might make the system work, and even pay, without aid from the State. If, however, a small grant or loan were necessary to start with, it should be easily possible to refund it within an appointed time.

CARBOLIC ACID AS A SAFEGUARD AGAINST INSECTS.

MANY people do not know how easily they can protect themselves and their children against the bites of gnats and other insects. Weak carbolic acid sponged on the skin and hair, and in some cases the clothing, will drive away the whole tribe. A great many children and not a few adults are tormented throughout the whole summer by minute enemies. We know persons who are afraid of picnics and even of their own gardens on this account. Clothing is an imperfect protection, for we have seen a child whose foot and ankle had been stung through the stocking so seriously that for days she could not wear a leather shoe. All this can be averted according to our experience, and that we believe of many others, by carbolic acid judiciously used. The safest plan is to keep a saturated solution of the acid. The solution cannot contain more than 6 or 7 per cent., and it may be added to water until the latter smells strongly. This may readily, and with perfect safety, be applied with a sponge. We have no doubt that horses and cattle could be protected in the same way from the flies, which sometimes nearly madden them, and it even seems possible that that terrible scourge the African Tsetse fly, might be kept off in the same manner.

DEATH FROM CHLOROFORM AND FEAR.

AN inquest recently held at University College Hospital on the body of a woman forty-one years of age opens up two important questions bearing upon the administration of volatile narcotics under special circumstances of disease. The patient had suffered from pleurisy, followed by effusion of serum into the left pleural cavity, and the operation to which she was subjected was that of tapping the chest in order to draw off the fluid. The needle was inserted, but as the fluid did not flow it was proposed to tap at a point lower down. To quiet the anxiety of the patient, who had become nervous, and who asked for chloroform for the second puncture, chloroform was administered, but before the quantity put into the inhaler—about two drachms—was used up, the pulse stopped and death followed. In order to give a chance of recovery, the fluid was drawn off from the chest, and the other usual means of restoration were supplied, but without avail. The post-mortem showed the heart to be fatty and empty, and death was returned as from syncope under chloroform. The two practical questions in connexion with this untoward event are: (1) Is it extra hazardous to administer an anæsthetic when a pleural cavity is charged with fluid? (2) Is it extra hazardous to administer an anæsthetic like chloroform after a patient has expressed fear or anxiety during an operation? In answer to the first question, we should infer—although the matter has, we admit, been little argued—that in all cases

Digitized by Google

where the capacity of the chest is reduced by effusion of fluid or other cause there is some extra risk, and that in such cases local anæsthesia is the safest method. On the second question we have less doubt. We believe, as we before expressed in these columns, that it is always an extra risk to administer chloroform when a patient is becoming faint or nervous from fear. Chloroform acts on the heart like fear, and had better be avoided when nervous trepidation leading to faintness is present. We do not for a moment say that this patient would not have died under any other method of anæsthesia, or that she might not have died if no anæsthetic had been employed. But in the future it may perhaps be preferable, guided by the experience here afforded, not to administer chloroform under any persuasion of the patient, when, with reduced capacity of respiration from mechanical impediment, there is nervous shock and threatened syncope from fear.

JUBILEE HONOURS TO MEDICAL MEN.

The *Gazette* published on the eve of Jubilee Day did *not* chronicle the fact of a peerage having been allotted to any medical man. Well, the most we can say is that an opportunity has been allowed to slip. The fact remains that no member of our profession has ever been raised above the rank of a baronet. We are not disposed to magnify this grievance, but it is undoubtedly felt to be one, and it would have been an act of grace in this year of jubilee to wipe away the reproach that the practice of medicine disqualifies a man for very high social position. For the rest, the honours conferred on the profession, though scanty, are of a nature to be approved. Professor Garrod, always supposing he did not care to accept a baronetcy, is clearly entitled to knighthood. Mr. MacLeod will wear his new honours with credit. The other honours have been appropriately conferred. As a whole, the *Gazette* is a meagre one; but while many aspirants will be disappointed, there is nothing to be urged against the little that has been bestowed.

SPAYING FOR FIBROIDS.

DR. G. ZVORYKIN has collected statistics of nearly 300 cases of spaying (*kastratsia*) for uterine fibroids. A large proportion of these are from English and American sources; seven, however, are contributed by Russian surgeons, six by Dr. Zvorykin's chief, Professor Lebedeff, and one by Dr. Salmanoff. Two of them are described as interstitial, three as multiple interstitial, one as interstitial cavernous, and one as subserous multiple interstitial. In all these seven cases, both ovaries, and in three of them more or less of the tubes, were removed. The hæmorrhage from which all the patients had suffered ceased, and no bad symptoms occurred. Dr. Zvorykin compares spaying with myotomy, and believes the one to be as devoid of danger as the other. Spaying, he considers, is indicated in cavernous fibromata; in retro-cervical or inter-ligamentous tumours, where myotomy would be attended with danger; in all interstitial fibromata, especially in small ones where menorrhagia is the chief symptom; in subserous fibromata of large size, if they give rise to menorrhagia; and in cases where the patient has become so anæmic and weak that the loss of blood necessarily attendant on the operation of myotomy would be likely to affect her condition seriously. Spaying he considers contra-indicated in subserous fibroids with long pedicles which can easily be removed; in large interstitial fibroids causing symptoms of weight and bearing down, but unattended with menorrhagia; in fibro-cystic tumours; in young subjects in whom fertility may be restored after myotomy; and, lastly, in cases where the ovaries are enclosed in a mass of false membranes, and their removal is consequently attended with great difficulty.

THE HEALTH OF THE CROWN PRINCE.

HIS Imperial Highness the Crown Prince of Germany continues in excellent health, and the appearance of the larynx is quite satisfactory. There is now no congestion, though the ventricular bands are slightly relaxed. As the Crown Prince could not possibly manage to keep very quiet during the past week, Dr. Morell Mackenzie has not yet thought it desirable to perform another operation. He has, however, applied a solution of perchloride of iron on several occasions, and it is probable that some more of the growth will be removed early next week. Dr. Norris Wolfenden has, by desire of Dr. Mackenzie, been added to the resident medical staff in attendance on the Crown Prince at Norwood, in order that he may make applications to the larynx and report to Dr. Mackenzie on those days on which he does not examine the illustrious patient himself.

THE CEREBRAL CENTRES FOR GASTRIC MOVEMENTS.

DR. B. A. HLASKO, of Dorpat, has recently followed up some researches of Oppenchowski, Knaut, and Dobbert upon the mode in which the stomach is affected by cerebral influences. His experiments were conducted on no less than seventy-six dogs, by stimulating different regions of the brain by the faradaic current. He finds that the centre for the contraction of the cardiac extremity of the stomach are situated in the corpora quadrigemina, and that the nerve fibres connecting these centres with the cardiac pass in part down the spinal cord, but more especially along the pneumogastric. The centres for contraction of the sides of the stomach are likewise situated in the corpora quadrigemina, the impulses travelling mainly through the spinal cord. The centre for the dilatation of the cardia—i.e., the origin of Oppenchowski's "dilator nerve of the cardia"—is situated at the junction between the lenticular nucleus with the anterior inferior extremity of the caudate nucleus close to the anterior commissure. The vagus is here the medium of communication with the cardia. The cardio-dilator fibres found by Knaut in the spinal cord appear to originate from some other not yet known centre in the cord or brain. From these researches Dr. Hlasko is inclined to doubt the existence of a single "vomiting centre," such as is believed in by many. He thinks that the different actions on the stomach and the abdominal and respiratory muscles which are concerned in the act of vomiting are probably each governed by a different centre.

METROPOLITAN ASYLUMS BOARD.

THE report as to small-pox prevalence in the metropolis which was presented at the meeting of the Asylums Board on Saturday continues to be satisfactory. In the preceding fortnight not a single patient had been admitted. Two had been discharged, and one only remained under treatment. When the size of London is considered, the almost complete absence of this disease is in every way quite worthy. Scarlet fever however, has been distinctly prevalent, as many as 452 cases being in the hospitals of the Board together with five patients suffering from typhus and three from enteric fever. The Ambulance Committee has reported that so long as the hospital ships remain open for the reception of patients, no further modifications could be made with due regard to the efficiency of the ambulance service; and even if the ships were closed the staff would have to be maintained [illegible] fication for the protection of the [illegible] observe with satisfaction that the Board has received the honour of knighthood [illegible] the Queen's Jubilee. This people [illegible]

Digitized by Google

which are rendered to London by the hospital-providing authority for infectious diseases will give satisfaction to those who are cognisant of the difficulties against which the managers have to contend. It is indeed time that the complaints of other authorities as to the board's expenditure should cease. That there have been carelessness and extravagance in the past there is no matter for doubt; but London is dependent, as are other communities, upon hospital provision for the prevention of disease, and we congratulate Sir Edwin Galsworthy and his colleagues upon the estimation in which their efforts are held by Her Majesty and her responsible advisers.

THE JOHN LUCAS WALKER STUDENT IN PATHOLOGY.

DR. WM. HUNTER, M.D. Edin., F.R.S.E., &c., has been elected the first holder of this studentship. After a brilliant university career, culminating in the Ettles Scholarship, Dr. Hunter took his M.B. degree at Edinburgh in 1383. He then acted for six months as assistant to Prof. Rutherford, and for the following six months as one of the resident physicians in the University wards of the Edinburgh Royal Infirmary. Since that time he has been engaged in original work on pathology at Vienna, Leipzig, and Edinburgh. His graduation thesis for the degree of M.D. on "The Physiology and Pathology of Transfusion and the Fate of Extravasated Blood" was awarded a gold medal. Other papers giving an account of his researches—chiefly on the pathology of the blood—have appeared in the *Journal of Anatomy and Physiology* and elsewhere. Dr. Hunter's past success as an investigator of pathological problems, and the opportunities which he has had of becoming acquainted with experimental work as well as with morbid anatomy and histology, render him extremely well qualified to occupy worthily the post to which he has been elected.

THE HOSPITAL SUNDAY FUND.

IT is too soon to take any accurate view of the success of the Hospital Sunday Fund this year, and of the discussion of the merits of our hospital system which has taken place in connexion with the Hospital Sunday anniversary, wide and important beyond precedent. We shall not delay a week in acknowledging the earnestness and energy of all helpers, lay and clerical, but we shall defer comment till we have more data in our possession.

DYSACUSIS.

M. LANNOIS has contributed to the *Lyon Médical*, No. 24, an interesting article on hyperacusis in facial paralysis and on the influence of mastication on the acuity of hearing. Amongst some individuals a very notable diminution of the faculty of hearing may be detected during mastication, and this diminution may even amount to actual deafness, so that on addressing the masticating individual not a syllable reaches his consciousness. In some cases of facial paralysis a distressing sensation in the ear of the paralysed side may be experienced, and this has gone incorrectly by the name of hyperacusis. The tensor tympani or internal muscle of the malleus receives its nerve supply through a small branch from the otic ganglion on the third part of the fifth nerve. It is held, therefore, that in paralysis of the facial nerve the auditory phenomenon is due to concomitant paralysis of the stapedius, which is believed to be supplied by the facial nerve, but this nerve does not supply the tensor tympani. The diminished auditory capacity observed in some individuals during contraction of the masseter and other muscles supplied by the motor part of the fifth nerve is the result of a simultaneous but too energetic contraction of the tensor tympani, which is innervated motorially by the fifth nerve also.

MEDICAL RELIEF IN GLASGOW AND THE CHARITY ORGANISATION SOCIETY.

FOR some time past the families of the able-bodied poor have been attended by a medical practitioner appointed by the above Society for this purpose, and paid by it. The Society considers this provision essentially temporary, and now seeks to throw the duty of medically attending the able-bodied poor on the various medical charitable agencies, notably on the Glasgow Medical Mission, as "admirably suited for affording suitable attention to that class of the poor." The Charity Organisation Society will still investigate the cases. The question is a difficult one, the only thing clear being that society at large should pay for this attendance, and not throw it on the gratuitous services of the profession.

THE HOSPITAL SATURDAY FUND.

THE results of the recent Hospital Saturday collection, as so far announced, are still very unsatisfactory. The sum collected in factories was £6675 5*s.*, and by ladies in the streets £145 1*s.* 6*d.*, a total of £6820 6*s.* 6*d.*, against £6702 9*s.* 3*d.* last year. There will be no adequate success in this matter till the committee of the Hospital Saturday Fund takes into its serious consideration the methods practised by similar committees in Birmingham, Sheffield, Sunderland, and other provincial towns.

DEATHS OF EMINENT FOREIGN MEDICAL AND SCIENTIFIC MEN.

THE deaths of the following foreign medical and scientific men are announced:—Dr. Eduard Heymann, Geheimer Sanitätsrath, of Berlin, at the age of seventy-one.—Dr. Gustav Hauck, Geheimer Sanitätsrath, of Berlin, at the age of seventy-six.—Dr. D. Jaime Vilar y Colom, editor of the Spanish medical journal, *La Lanceta*, published at Barcelona.—Dr. T. R. Pasternatski, *docent* of mental diseases in Warsaw, at the age of thirty-nine.—Dr. A. Zagumeni of St. Petersburg, having after many fruitless endeavours failed in obtaining a professorship of chemistry in Warsaw, Kieff, or St. Petersburg, poisoned himself with prussic acid. He was forty-two years of age, a Doctor of Medicine, Master of Chemistry, and "Laborant" of the Academy of Sciences.

THE REMOVAL OF A SPINAL TUMOUR.

WE are glad to be able to report the continued good progress towards recovery of the patient from whom the tumour was removed from the spinal canal on June 9th, a short account of which we gave in our issue of the 18th (p. 1244). Comparatively little improvement in the condition of the lower extremities has as yet been noted, and there is much discharge of cerebro-spinal fluid from the wound, but the temperature indicates an aseptic course, whilst the general condition of the patient is improving.

OXIDISING ACTION OF TURPENTINE ON ALCOHOL.

IN the method of preserving biological specimens proposed by Mr. M'Alpine of Melbourne, which consists in abstracting their moisture with alcohol after hardening in chromic acid, and then placing the specimen in turpentine for some time, great discrepancies are found to arise according as the alcohol is or is not allowed to evaporate from the specimen before dipping it into the turpentine. An explanation of this discrepancy has just been suggested by some recent experiments of Mr. Steedman of Victoria, who finds that dilute ethyl alcohol becomes oxidised to acetic acid in presence of air and turpentine. Thus a clear glass 16-oz. bottle containing two drachms of alcohol one drachm of turpentine,

Digitized by Google

and one ounce of water, corked securely, and left exposed to a temperature averaging about 80° F. for three months, was found to contain a liquid which was decidedly acid from the presence of acetic acid.

SINE CURRICULO DENTAL EXAMINATIONS.

AT last the Royal College of Surgeons of Edinburgh have given notice that they will close their doors to *sine curriculo* men for the dental examination after the end of next year, and we sincerely hope that the Irish College and the Faculty of Physicians and Surgeons of Glasgow will do the same. It is now nine years (less one month) since the passing of the Dentists Act: surely that is sufficient time for any man in practice to prepare for and pass the Licentiateship in Dental Surgery. Not only can no good accrue either to the dental profession or to the general public by the examining boards admitting men who have not had a hospital training, but they lay themselves open to the charge of being actuated by pecuniary motives.

QUEEN'S COLLEGE, BIRMINGHAM.

AT a meeting of the Council on the 16th inst., Mr. Bennett May, F.R.C.S., B.S., surgeon to Queen's Hospital, was elected to the chair of Professor of Surgery, to fill the vacancy caused by the resignation of Mr. Furneaux Jordan.

DIPHTHERIA IN ONTARIO.

GREAT prominence is given in the last annual report of the Provincial Board of Health of Ontario to the history and causes of diphtheria, that disease having prevailed during 1886 in the area under the Board's jurisdiction to an extent unprecedented and unequalled in the history of the province. The death-rate reached 0·76 per 1000 of the population, the total deaths having been 1470. The etiology of the disease is discussed at considerable length, and the views of German, English, and other authorities are referred to. Regulations as to the prevention of the infection, such as have been drafted by the Provincial Board, are also set forth in detail. Dr. Chas. W. Covernton, chairman of the Board, also deals with the subject in his introductory chapter as to the matters which have occupied the attention of the Board during the year reported on.

DRY HOT-AIR BATHS FOR SYPHILITIC PATIENTS.

DR. STEPANOFF of Moscow has contrived a plan of treating patients suffering from syphilis which has resisted mercurial and iodine treatment. He has had a box or bath constructed with an iron bottom lined with thick felt, in which the patient is placed. The bath is heated to about 170° to 190° F. by means of two Bunsen's lamps, each consisting of five burners. After the patient has been "baked" he is put to bed and covered with blankets, so as to prolong the sweating process commenced in the bath for an extra half-hour. After this he is allowed to dress and go into the ward to his dinner. By means of these baths the mercury is rapidly eliminated from the system and the patient's condition greatly improves, and after a course mercury is found to act quickly and energetically.

THE CHEMICAL EQUIVALENT OF ZINC.

LIEUT.-COL. REYNOLDS and PROFESSOR RAMSAY have communicated to the Chemical Society the result of a series of twenty-nine experiments, conducted with great care, with the object of determining the exact equivalent of zinc. The zinc used was prepared by electrolysis from sulphate of zinc, the final sample being so nearly pure that dilute acid would scarcely act on it. The equivalent arrived at was 65·4787 + 0·016135.

FOREIGN UNIVERSITY INTELLIGENCE.

Dorpat.—Dr. Friedreich Schultze, Extraordinary Professor in Heidelberg, has been offered the chair of Special Pathology and Therapeutics, vacated by Professor A. Weil on account of ill health.

Kasan.—Dr. Bogoluboff, Professor of Clinical Surgery, is about to retire in consequence of ill health. The *Vratch* understands that the chair will be given to Dr. V. T. Razumovski, *privat docent* for Operative Surgery in the same University.

Leipsig. — Professor de Bary of Strasburg has been appointed to the Professorship of Botany.

Madrid.—Notice has just been given that a *concurso* is to be held immediately, for the selection of the directors of, and assistants in, the medico-legal laboratories of Madrid, Barcelona, and Seville, which institutions were established, on paper at least, about a year ago.

Poitiers.—M. le Dr. Buffet-Delmas has been appointed acting Professor of Anatomy and Physiology.

Prague.—A memorial which has recently been presented to the Berlin authorities, requesting that study in Prague might be recognised in the case of students of German nationality has not been acceded to.

St. Petersburg (Military Medical Academy).—Dr. Tarenetski, Prosector of Anatomy, has been appointed to the Professorship of the same subject, vacated by Professor V. Gruber. Professor T. T. Nasiloff was also appointed to the chair of Surgery lately held by Professor Kolomnin, deceased.

THE repetition of the Jubilee service in Westminster Abbey on the 22nd inst. was attended by a large congregation. As we announced in our last issue, the admissions were in great part by ticket, given in consideration of donations for hospital assistance. A third of the receipts go to Westminster Hospital, whose secretary has sustained the chief burden of the arrangements; a third to the Hospital Sunday Fund; and a third to the Western Dispensary and the Hospital Saturday Fund jointly.

WE learn that the report published by an evening contemporary a few days ago, to the effect that measles was very prevalent amongst the boys in Winchester College, was exaggerated. There are a few cases of German measles in the school sanatorium, but, contrary to what had been stated, the cricket match between Winchester and Eton has not been postponed, but commences this day (Friday).

MR. F. J. WILLIAMSON, of Esher, has been entrusted with the commission of executing the marble statue of the Queen, which the Royal Colleges of Physicians and Surgeons have resolved to place in the Examination Hall to celebrate the Jubilee of Her Majesty's reign. It is to be finished by June of next year and will be placed on the half-landing facing the entrance to the Hall.

A GENERAL meeting of the Zoological Society of London was held on the 16th inst., on the lawn of the Society's gardens, which was reserved for the occasion. Professor Flower, the president, delivered an address in which he reviewed the history of the Zoological Society from its foundation in the year 1826.

CHOLERA is stated to be again spreading rapidly in Tonkin. The circumstance is all the more important because it was from Tonkin that cholera was first imported into the military port of Toulon, whence resulted the serious epidemic of 1884-86.

JUBILEE MEDICAL HONOURS.

THE QUEEN, on the occasion of Her Majesty's Jubilee, has been graciously pleased to order the following appointments and promotions to be made:—

Knights.

Dr. Garrod.
G. H. MacLeod, Esq., Queen's Surgeon, Edinburgh.
Dr. Aitken, Netley Hospital.

ORDER OF THE BATH.

Ordinary Member of the Military Division of the Second Class, or Knights Commanders.

Surgeon-General John Harrie Ker Innes, C.B., Honorary Surgeon to the Queen.

Additional Members of the Military Division of the Second Class, or Knights Commanders.

Inspector-General of Hospitals William Mackenzie, M.D., C.B., C.S.I., Indian Medical Service, Honorary Physician to the Queen.

Inspector-General of Hospitals and Fleets James Jenkins, C.B., Royal Navy.

Knights Commanders (Civil Division).

John Simon, Esq., M.D., C.B., late Medical Officer, Privy Council Office.

Dr. Arthur Mitchell, M.D., C.B., Lunacy Commissioner, Scotland.

Ordinary Members of the Military Division of the Third Class, or Companions.

Inspector-General of Hospitals and Fleets James Nicholas Dick, Royal Navy.

Surgeon-General Herbert Taylor Reade, V.C., Medical Staff.

Deputy Surgeon-General Jeffery Allen Marston, M.D., Medical Staff.

An Ordinary Member of the Civil Division of the Third Class, or Companion.

Professor W. H. Flower, British Museum.

ORDER OF ST. MICHAEL AND ST. GEORGE.

Ordinary Member of the Second Class, or Knight Commander

James Alexander Grant, Esq., M.D., of Ottawa, in the Dominion of Canada.

Companion.

Sir Oscar Clayton.

The Queen has been pleased to give orders for the appointment of the undermentioned officer to be a Companion of the "Distinguished Service Order":—

For Operations in Burmah.

Fleet-Surgeon Thomas D'Arcy Bromlow, M.D., Royal Navy.

The Queen has been graciously pleased to confer the decoration of the Royal Red Cross upon the undermentioned Nursing Sisters under the provisions of Clause 5 of Her Majesty's Warrant, dated April 23rd, 1883:—Miss Louisa Jane Mackay, Army Nursing Sister; Miss Christina Fergusson, Army Nursing Sister; Miss A. B. Holland, Army Nursing Sister; Miss Edith King, Stafford-house Committee; Miss Emma Durham, Stafford-house Committee.

The following members of the Veterinary profession have also participated in the distribution of honours:—

Knight

H. L. Simpson, Esq., Mayor of Windsor, President of the Royal Veterinary College.

Ordinary Members of the Civil Division of the Third Class or Companions of the Order of the Bath.

Principal Veterinary Surgeon George Fleming, Head-Quarters Staff of the Army.

Professor Brown, Agricultural Department of the Privy Council.

A MR. D. O. MILLS has given 80,000 dols. for the purpose of erecting a new building on the grounds of Bellevue Hospital, New York, which will be used mainly as a training school for male nurses.

THE HOSPITAL SUNDAY FUND.

ON the 16th inst. a public meeting in aid of the Hospital Sunday Fund was held at Wellington Hall, Islington. The Islington north and north-west district contains eleven hospitals and six dispensaries benefiting from the fund. In 1886 these institutions relieved 6243 in-patients and 105,849 out-patients; their total income was £52,581 and their total expenditure £60,346. The chair was taken by the Rev. H. W. Barlow (Vicar of Islington), who was supported by Sir A. K. Rollit, M.P., the Rev. Canon Hurst, the Rev. Dr. Allon, the Hon. Conrad Dillon, and others. The chairman having briefly opened the meeting, Sir Albert Rollit, M.P., moved the first resolution, insisting upon the importance of maintaining the hospitals in the utmost efficiency, and urging the clergy to earnestly appeal to their congregations in order to secure that the whole sum collected on Hospital Sunday should not be less than £100,000. He said that the great deficiencies which had arisen in the funds of the hospitals were a breach in the continuity of the history of the century. At the beginning of the century there were only 51 of these institutions, and at present there were 496 scattered over the United Kingdom. This was a thing to be proud of, and was characteristic of the humane spirit of the age. The Hon. Conrad Dillon seconded the resolution, pointing out that the sanitary education given by the hospitals was very great. The motion having been carried, the Rev. Canon Hurst moved the second resolution, regretting that in the year 1886 the deficit of the hospitals in that district amounted to £8000, and pledging the meeting to increased exertion to prevent a repetition of the deficiency. Dr. Glover seconded the resolution. He said that the hospital accommodation of London at present was barely sufficient to meet the cases of urgent necessity, while cases of chronic disease had to suffer in consequence. The expenditure of the hospitals was very narrowly watched nowadays by business men, and extravagance was almost impossible. The resolution was carried, and the meeting terminated with a vote of thanks to the chairman.

On the 17th inst. a meeting was held at Stratford Town-hall. The Stratford and East-end district contains seven hospitals and five dispensaries benefiting under the fund. In 1886 these institutions relieved 14,190 in-patients and 189,401 out-patients; their total income was £78,565 and their total expenditure £109,399. The chair was taken by Mr. John Meeson, Mayor of Stratford. Lord Rosebery moved the first resolution, which was similar to the one moved by Sir Albert Rollit, M.P., at Islington on the 16th inst. He said that if we are to continue facing a deficit every year with regard to hospitals, the natural result would be that they must come upon the rates. This he was not in favour of, for two reasons—one being that the rates are high enough already, and the second because he believed that the best of all energy and of all motive powers is voluntary effort. Zeal cannot be bought. Again, where subscriptions are voluntary the subscribers look out very closely to see that their money is well spent. Lord Rosebery expressed the opinion that this was not the case with rate-supported hospitals, and alluded to the recent disclosures respecting the management and expenditure of the Eastern Hospital. Canon Scott, Sir Edmund Hay Currie, Mr. Forrest Fulton, and others also addressed the meeting.

In the afternoon of the same day another meeting was held at Westminster Town-hall, the Dean of Westminster presiding, and resolutions were passed similar to those passed at all the previous meetings.

On the 18th inst. the last of the series of meetings was held at the People's Palace, under the Presidency of the Duke of Cambridge. Among those present were the Right Hon. C. T. Ritchie, (M.P.), Sir Edmund Hay Currie, the Bishop of Bedford, Mr. J. H. Buxton, Mr. H. C. Burdett, and Canon Scott. The chairman, in opening the proceedings, referred to the great and useful work carried on by the hospitals. More especially, he said, were those institutions deserving of liberal public support in the East-end, for it was there that their assistance was most essential. He concluded by moving the usual resolution. Mr. Ritchie, M.P., in seconding the motion, said that he trusted that the public would do away with the scandalous state of things under which the hospitals were spending £100,000 a year more than they received. The resolution having been supported by the

Digitized by Google

Bishop of Bedford, it was carried unanimously. Sir Edmund Hay Currie then moved a second resolution, regretting that the deficit in the accounts of the hospitals of East London amounted to £30,000 in the year 1886. He said that there were no fewer than 2100 beds unoccupied in the eastern hospitals. Mr. J. H. Buxton seconded the resolution, which was also carried unanimously. A vote of thanks to the chairman having been carried with acclamation and briefly acknowledged, the meeting terminated.

On the 19th inst. the annual collections were made at nearly all the churches, and other places of worship in the metropolis. The congregations were as a rule good, especially in the West-end, the large number of visitors in town for the jubilee festivities having a marked effect upon the ordinary attendance.

The following is a list of the principal contributions which have up to the time of our going to press been received by the secretary of the fund:—St. Michael, Chester-square (Rev. Canon Fleming, B.D.), £1023; St. Jude's (Rev. D. Forrest), £800; St. Paul's Cathedral, £232; Holy Trinity, Kilburn, £81; St. John the Evangelist, Penge, £85; St. Peter's, Brockley, £69; St. Matthew's, Brixton-hill, £70; All Saints', Blackheath, £75; Dulwich College Chapel, £50; St. Marylebone Presbyterian Church, £56; Barnes, Surrey, Parish Church, £54; Amelia, Countess of Lauderdale, £50; St. Mark's, North Audley-street, £146; St. Saviour's, Pimlico, £52; St. Mark's, Reigate, £84; Brixton Unitarian Church, £58; St. Paul's, Forest-hill, £66; St. Andrew's, Wells-street, £114; St. John's, Clapham-rise, £61; Trinity Church, Hampstead, with St. Cuthbert's, £91; St. Michael's Parish Church, Highgate, £66; All Saints', Margaret-street, £70; Metropolitan Tabernacle (Rev. C. H. Spurgeon), £250; St. Matthew's, Denmark-hill, £56; St. Matthew and Holy Trinity Missions, Upper Clapton, E., £100; Mr. James Carnegie, £50; the Temple Church, £273; St. Stephen's, Wandsworth, £60; City Temple, £58; Clapton Park Congregational Chapel, £100; Christ Church, Highbury, £113; All Saints', Ennismore Gardens, £357; St. Mark, Hamilton-terrace, £295; St. Paul's, South Hampstead, £104; St. Paul's Presbyterian Church, Westbourne Grove, £63; Hampstead Parish Church, £70; Westminster Abbey (afternoon service at St. Margaret's), £58; St. Stephen's, Ealing, £129; Christ Church, St. Marylebone, £62; St. Paul's, Clapham, £50; St. Peter's, Dulwich Common, and St. Dunstan's, £51; St. James's, Kidbrook, £141; St. John's Presbyterian Church, Forest-hill, £87; Clapham Parish Church, £58; St. James's, Piccadilly, £132; Holy Trinity, Sydenham, £120; Brixton-hill Wesleyan Chapel and Schools, £79; St. James's, Paddington, £189; Trinity, St. Marylebone, £84; Lewisham High-road Congregational Church, £57; Sir W. B. Gurdon, £50; St. Mary's New Church, Stoke Newington, £58.

The secretary of the Fund has also received £820, being the third, less expenses, of the receipts derived from the repetition of the Jubilee service in Westminster Abbey on the 22nd inst.

According to the last reports received previous to our going to press the sum total of the subscriptions up to that time amounted to over £12,000.

THE CROWN PRINCE OF GERMANY: NATURE OF THE LARYNGEAL GROWTH.

THE following is a translation of the report (published in the *Berliner Klinische Wochenschrift*, No. 25, June 20th, 1887, and forwarded to that journal by the physician to his Imperial and Royal Highness the Crown Prince, General Physician Dr. Wegner) "of Privy Councillor and Professor Dr. Virchow, upon fragments of a swelling in the larynx which have been removed by Dr. Morell Mackenzie from his Imperial and Royal Highness the Crown Prince by means of avulsion (*Zangenoperation*)." The report runs as follows:—

The two specimens delivered yesterday by General-Physician Dr. Wegner exhibit, on macroscopic inspection, the appearance of a coarsely granular papillated tumour. Their convex surface had a glandular, bluish-white, slightly transparent, glistening aspect, in so far as they retained their natural conditions; large portions, indeed, which had been acted upon by catechu showed a dull, brownish, somewhat crumbling character. The cut surfaces were somewhat retracted, and concealed by the turning up of the margins; they consisted of a soft, slightly fibrillated tissue, from which projected some shreds of various lengths. The larger of the two portions was 3 mm. in height, and had a diameter of 2·5 mm.; the smaller was about 2 mm. in diameter. However, these measurements could not have quite corresponded to the conditions during life, for by the retraction and infolding of the cut surfaces after extirpation they must have undergone a diminution. Microscopical examination confirmed the diagnosis made by the naked-eye inspection:—1. The surface everywhere consisted of a very firm and thick layer of stratified squamous epithelium. Large colloid granules appeared in many of the cells. Here and there lay a nest of concentrically laminated cells. Internally there occurred a similar stratified layer of cylindrical cells (without cilia), which were seated directly on the connective tissue. 2. The connective tissue layer of the mucous membrane was furnished on its surface with long papillary outgrowths, which contained large vascular loops besides the connective tissue elements. Each such papilla corresponded to a granulation on the surface. Otherwise the mucous membrane showed scarcely any changes; even proliferation of nuclei and cells were only sparsely detected. The blood-vessels were moderately dilated. Both sections have been made deeply into the mucous membrane, and through this into the submucosa. Hence there are found, besides connective tissue with numerous fine elastic fibres, a large number of small nerve-trunks (from four to six fibres) and their branches, as well as small arteries and veins; in some places are seen also collections of lobules of the mucous glands. Although it is thereby proved that the operation had reached the deep parts underlying the mucous membrane, yet in spite of the most careful examination of these deeper parts, especially at the cut surfaces, no single portions could be found altered in an appreciable degree. All such changes were confined to the surface. They characterise the lesion as an epithelial growth combined with papillary offshoots (misnamed papilloma)—*pachydermia verrucosa*. In no part could an ingrowth of this epithelial formation into the mucous membrane be detected.

The foregoing statement is an important advance upon the statement of the 21st of May. In the specimen then examined changes resembling those now present were only very scanty in comparison with irritative changes, but all such appearances were limited to the periphery of the lesion. Now, on the other hand, a more central portion of the growth has apparently been obtained. Although this portion is very much diseased, yet the healthy condition of the tissue on the cut surface allows a very favourable opinion to be formed as to prognosis. Whether such an opinion would be justified in respect to the whole disease cannot be ascertained with certainty from the two portions removed. However, there is nothing present in them which would be likely to excite the suspicion of wider and graver disease. (Signed) PROF. DR. RUD. VIRCHOW.

Berlin Pathological Institute, June 9th, 1887.

LOCK HOSPITALS.

THAT part of the report of the Dublin Hospitals' Commission which refers to the Westmoreland Lock Hospital is of great importance not only to all concerned in the working of the hospital itself, but also as it bears upon the important question of hospital accommodation for patients with venereal diseases. It may appear to medical readers somewhat late in the day to be raising such a question, but, as we shall see, it is not only still a question, but a veritable *vexata quæstio*, surrounded with difficulties which appear to be almost insuperable. The commissioners first allude to the reports of a former Commission and Select Committee, both of which recommended that, as the Westmoreland Lock Hospital received assistance from the State, students should be admitted for the purpose of receiving clinical instruction, which recommendation, however, has not been complied with. The reasons for this are next dealt with. The governors of the hospital, who were responsible for the carrying out of this as of the other recommendations, were against the admission of

Digitized by Google

students. Dr. Donnelly, the resident surgeon of the hospital, while admitting the importance of students having clinical instruction, expressed his opinion that it would not be practicable, and would deter the women from entering. Dr. Henry Fitzgibbon did not go quite so far as this; but Mr. Reginald Harrison, surgeon to the Liverpool Royal Infirmary, was enabled to give the commissioners important evidence on this point from the experience of the Liverpool Lock Hospital, which is a part of the Royal Infirmary. There it was found that the admission of students did deter women from entering, and when the former were excluded from the female side some years ago there was a marked increase in the number of female patients. In spite, however, of this, and of the fact which was also given in evidence that the examining medical authorities do not require certificates of attendance upon such institutions (i.e., lock hospitals), the commissioners report as follows:—

"Having regard, however, to the fact that this hospital 'does not,' to quote the words of the select committee, 'afford medical instruction,' we are clearly of opinion that it has forfeited its claim to participate any longer in the Parliamentary grant in its present form; while it is clear that, if our recommendation should be adopted, it will be excluded from any share in the newly created fund so long as it abstains from affording this instruction; and, further, that even if it were to comply with the condition upon which alone any hospital in Dublin will in future obtain an allotment from the fund, the amount to be allotted to it must inevitably be too small to admit of its continuing to exist without support from other sources. We are therefore brought face to face with the question as to how this hospital is to be supported in the almost certain event of the Parliamentary grant in its present form being discontinued."

There is, to say the least, a want of reasoning throughout the whole of this paragraph, which is very remarkable in so important a document, upon which such very weighty issues depend. To disestablish and disendow a hospital, which is admitted to be well managed, and which fulfils the object for which it was founded, because it does not afford clinical instruction, which the examining bodies do not require, and which comparatively few students would seek, is illogical in the extreme. But with the evidence before them, that the governors would not sanction the admission of students, and the great probability that this would deter patients from entering, the paragraph becomes worse than illogical—it is, indeed, wholly unjustifiable. Should the Westmoreland Lock Hospital be closed for this reason only, it would be nothing short of a scandal. The commissioners evidently feel this for they proceed:—

"That Parliament will again consent to place the Lock Hospital in Dublin in the singular position of being the only hospital of the kind which is supported by moneys charged on a vote included in the estimates for Civil Services, is in the highest degree improbable.....How, then, is this hospital to be supported in future? It is plain that there are but two ways in which it can be done—the one by private charity, the other by local rates; but it seems to be generally admitted that an appeal to the public would be in vain, and if this view be well founded, it is certain that the hospital must be closed unless it can be supported out of the rates. That this will be the ultimate solution we can hardly doubt, and we believe that it will in various ways be attended with great benefits, moral and material, to the community at large."

With the exception that Dr. Thomas Myles was secretary, the Commission appears to have been wholly composed of laymen. Had the Commission been a medical one, its members would probably have congratulated Dublin on possessing so valuable an institution as a lock hospital supported by Government, and have suggested, not its abolition nor its disendowment, but its initiation in other towns and cities, especially such as, like Dublin, are garrison cities and seaports. The commissioners rightly conclude that the public are not likely to take up the duty of supporting this hospital after the Government have given it up, but the suggestion that the ratepayers should be called upon to support the hospital does not indicate the same amount of knowledge of the world which might have been expected of them. What reason have they to assume that the public will do compulsorily as ratepayers that which they will not do voluntarily as individuals and philanthropists? It is true that destitute persons suffering from venereal diseases are admitted into workhouses, but they are admitted because they are paupers; and it is only as such that they are admissible at all. Thirty years ago the late Mr. Acton made a proposal somewhat similar to that suggested by the Dublin Commission, of the reception of which he gives a brief and plaintive description: "My so-styled 'preposterous idea' that the overtaxed ratepayers—many of them hardly able to support themselves—should be called upon actually to search out and then maintain in idleness a parcel of invalid harlots, thus qualifying them for fresh campaigns against the public, was duly sifted over and ridiculed, and its unlucky author was dismissed to keep the company of other visionaries." By the repeal of the Contagious Diseases Acts the Government Lock Hospitals at Kildare (Curragh Camp) and Cork have been closed. Should the Westmoreland Lock Hospital be also closed, as appears only too probable, Ireland will be without any lock hospitals at all—a great disaster, since the lock wards of its general hospitals are so few, so far between, and contain so few beds as to be a mere "drop in the bucket."

Let us turn to London and see what has been done there in the way of lock hospital and lock ward accommodation. The London Lock Hospital was founded in 1747 in Grosvenor-place, and removed to Westbourne-green in 1846; the hospital for male patients being opened in Dean-street, Soho, in 1862. In spite of this ancient history, the patronage of Royalty and of the nobility, and the fact of its being the only hospital of the kind in London, its very existence has from the first been one continued struggle; and but for the almost superhuman exertions of the late Lord Kinnaird and the partial support of the Government, it must long ago have been closed. As it is, the withdrawal of the Government grant will affect the hospital finances very seriously. Passing on to the lock wards in the general hospitals, it appears that in six hospitals—those of Guy's, King's College, the Royal Free, St. Bartholomew's, St. Thomas's, and the Middlesex, there has been a reduction in the beds for females of 97. Thus Guy's Hospital had formerly 30 beds, King's College 6, the Royal Free 30; now there are no beds for females with venereal diseases in any of these hospitals. Again, the beds in St. Bartholomew's Hospital have been reduced from 50 to 14; in St. Thomas's, from 30 to 28; in Middlesex, from 8 to 7. The London Hospital has 8 beds for female venereal cases. In all the other London Hospitals—Charing-cross, St. George's, St. Mary's, University College, and Westminster Hospitals, lock wards are conspicuous by their absence. The Lock Hospital has 36 beds made up for females, which, if the funds permitted, could be increased to 68. The lock wards in all the other London hospitals contain an aggregate of 57 beds; thus 93 is the total number of beds available in the whole of London for the many females who must at any given time be more or less afflicted with these diseases.

Passing on to other parts of the kingdom, we find the same deplorable dearth of lock hospitals and lock wards. There is the Glasgow Lock Hospital, for females only, with 60 beds available, which could be increased to 81. Manchester has a female lock hospital, with 20 beds made up and a capacity for 60. The Liverpool Lock Hospital of the Royal Infirmary (now temporarily closed) had 25 male and 25 female beds. The Bristol Lock Hospital, for females only, has 16 beds. There are lock wards in the Aberdeen Royal Infirmary (8 beds), Edinburgh Royal Infirmary (16 beds), Queen's Hospital, Birmingham (7 beds), Devon and Exeter Hospital (6 beds), Newcastle-on-Tyne Infirmary (12 beds), and Stafford General Infirmary (2 beds)—a total of 51 beds for females in six large and important hospitals. The same hospitals contain male wards with a total of 35 beds, increased recently by new male lock wards in the Edinburgh Royal Infirmary.

All this shows very conclusively that, unless a very great change takes place in public opinion, lock hospitals and lock wards will never be supplied or supported by the public in anything like a reasonable proportion to their necessity. Whether they will receive any share of the flow of charity during this Jubilee year remains to be seen, but it is very doubtful. When such great difficulties are experienced in raising funds for hospitals and other institutions for the most deserving inmates, it is obvious that these difficulties are increased when the patients are either dissolute men or common prostitutes. And though it has been frequently shown that married women infected by their husbands form a proportion of the patients in lock hospitals and wards, this does not seem to enhance the latter in public favour. The truth is that it is another illustration of the old saying, "What is everyone's business is nobody's business." The medical profession ought long

Digitized by Google

ago to have demanded through the examining bodies the compulsory practical study of, and examination in, these diseases; until this is done the public will not be convinced of the necessity of lock hospitals and wards. The male wards should be open to clinical instruction. Female wards cannot be so open to students; there are obvious difficulties in the way which need not be discussed. But under stringent regulations advanced students previously to their final examinations might be permitted to witness the examination of a few female patients, which is all that would be required. The arrangements of the Liverpool Lock Hospital, which were described by Mr. Harrison to the Dublin Commission, possess many advantages, notably those of economy combined with isolation. The patients are in a separate building, with its own surgical and administrative staff, but under the management of the committee of the Royal Infirmary. Before it is again proposed to support lock hospitals out of the rates, it is well that we should know what are the present arrangements in our existing workhouses. A return showing the average annual number of paupers admitted with venereal disease, whether they are admitted into special or general wards, and other details, would be of great interest, and we hope that such a return will be moved for.

MEMORIAL PORTRAIT OF SIR WILLIAM JENNER, BART., K.C.B., M.D.

THE following is a list of names of members of the General Committee additional to those already published:—

Acland, Sir Henry, K.C.B., Oxford.
Bagshawe, Dr., St. Leonards.
Batten, Dr., Gloucester.
Beale, Dr., Grosvenor-street.
Church, Dr. W. T., Harley-street.
Cooper, Alfred, Esq., Henrietta-street.
Critchett, J. A., Esq., Harley-street.
Falls, Dr., Bournemouth.
Fincham, Dr., Belgrave-road.
Fowler, Dr. J. K., Clarges-street.
Glover, Dr. J. G., Highbury.
Grigg, Dr., Curzon-street.
Habershon, Dr., Brook-street.
Jackson, Dr., Notting-hill.
Johnson, Dr. George, Savile-row.
Lawrence, Dr. H. C., Oxford-terrace.
Manifold, Surgeon-General, Cathcart-road.
Matterson, Dr., York.
Millington, Dr., Wolverhampton.
Morison, Dr. A., Highbury.
Odling, Dr., Oxford.
O'Neill, Dr., Lincoln.
Ord, Dr., Upper Brook-street.
Palmer, Dr., East Sheen.
Potter, Dr. J. B., George-street.
Priestley, Dr., Hertford-street.
Pye-Smith, Dr., Harley-street.
Roberts, Sir William, Manchester.
Savory, W. S., Esq., President, Royal College of Surgeons, Brook-street,
Sawyer, Sir James, Birmingham.
Scott, Dr. John, Chandos-street.
Semple, Dr. C. E., Torrington-square.
Sibley, S. B., Harley-street.
Smith, Dr. R., George-street.
Snow, Dr., Bournemouth.
Tirard, Dr., Weymouth-street.
Turner, Halifax.
Wakley, Thomas, Esq., Redcliffe-gardens.
Wakley, Thomas, Jun., Esq., Redcliffe-gardens.
Warner, Dr., Harley-street.
Weber, Dr. H., Grosvenor-street.
West, Dr. Symes, Croydon.
Whipham, Dr., Grosvenor-street.
Willcock, Dr., Manderville-street.
White, Dr., Weymouth-street.
Williams, Dr. C. T., Brook-street.

WILLS OF MEDICAL MEN.

THE will of Edward Nolloth, M.D., M.R.C.P., F.R.C.S., a retired Fleet Surgeon, R.N., late of 13, North-terrace, Camberwell, who died on April 29th last, was proved on May 11th by the Rev. Henry Edward Nolloth, one of the executors, the value of the personal estate amounting to upwards of £16,000. The testator gives £5000 and his furniture, plate, and household effects to his brother, Peter Brames Nolloth, £20 to his executor, and the residue of his property to his brother, Henry Ovenden Nolloth, and his two sisters in equal shares.

The will of Alfred Meadows, M.D. Lond., F.R.C.P., late of 27, George-street, Hanover-square, who died on April 19th last, was proved on May 11th by Mrs. Sara Stirling Meadows, the widow, the value of the personal estate amounting to over £15,000. The testator gives all his household furniture and effects to his wife. The residue of his property he leaves upon trust for his wife for life, and then to his daughter Anna Gertrude absolutely.

The will of Mr. William Tiffin Iliff, M.D., medical officer of health for St. Mary's, Newington, late of 37, Kennington-park-road, Surrey, who died on April 25th last, was proved on May 20th by Miss Louisa Susanna Iliff and Miss Ellen Agnes Iliff, the daughters, and Mr. Edward Chester, the executor, the value of the personal estate exceeding £8000. The testator gives legacies to his executors, servant, and Mr. Alfred Long, his faithful friend and invaluable assistant. The residue of his property he leaves to his seven children, Louisa Susannah, Ellen Agnes, Fanny, Eveleen, Lillian, Jessie Marrian, and Percy.

The will of Mr. Ralph Beardshaw, late of 2, De Grey-terrace, Leeds, Yorkshire, surgeon, who died on March 2nd last, was proved on May 11th, at the district registry, Wakefield, by Mr. Henry James Harrison and Mr. John Beardshaw, the executors, the value of the personal estate amounting to upwards of £3000. The testator leaves all his property upon trust to pay the annual income thereof to his three daughters, Mrs. Mary Helen Benham, Mrs. Harriet Dawson, and Margaret Ann, in equal shares, and after their death to their respective children.

The will of William Frederick Scoresby, M.D., late of Wawarsing, in the county of Ulster and State of New York, who died on November 17th, 1884, was proved in London on May 14th, by Mrs. Grace Ada Scoresby, the widow, John Frederick Scoresby Eastgate, the nephew, and George Halstead Smith, the executors, the value of the personal estate exceeding £3000. The testator gives the third share of his house and furniture to his wife for life, and all his medical books and instruments to his nephew, John Frederick Scoresby Eastgate. The residue of his real and personal estate he leaves upon trust for his wife for life, and at her death to his sisters, Mary Eastgate and Louisa Sherman, in equal shares.

The will, with a codicil, of Mr. George Bacon Sweeting, surgeon, late of King's Lynn, Norfolk, who died on March 25th last, was proved on May 12th by Miss Alice Helena Cox, the niece, and Mr. Charles Bagge Plowright, the executors, the value of the personal estate exceeding £2000. The testator gives £100 each to his nephews, Frederick Gould and George Gould; as to the residue of his property, he leaves one moiety to Mrs. Mary Ann Palmer Cox, and the other moiety to Mary Ann Elizabeth Sweeting and Robert Charles Sweeting, the children of his deceased brother, in equal shares.

The will, with a codicil, of Mr. William Henry Thornton, surgeon, late of Margate, Kent, who died on March 20th last, were proved on May 17th by Mrs. Ann Thornton, the widow, and Bertram Thornton, the son, the executors, the value of the personal estate amounting to over £5500. The testator, after bequeathing a legacy of £200 to his wife, leaves the residue of his real and personal estate upon trust for her for life, and after her death to his children absolutely.

The will of Geddes McKenzie Scott, M.D., late of 16, Stonebridge Park, Willesden, who died on April 11th last, was proved on May 19th by Mr. Thomas James Scott, the nephew, and Mr. Walter Brodie, the executors, the value of the personal estate in the United Kingdom amounting to £900. The testator gives legacies to grandchildren, and the residue of his property to the daughters of his son in equal shares.

The will of Vincent Ambler, M.D., late of No. 14, Colville-square, Bayswater, who died on February 6th last, was proved on May 13th by Mrs. Helena Ambler, the widow, the value of the personal estate exceeding £700. The testator leaves all his property upon trust, to pay the income thereof to his wife for the education and maintenance of his five children till they attain the age of twenty-one years, after which the principal is to be divided equally between his two daughters; his three sons, having a good education, will participate in other moneys. The testator leaves the piece of plate presented to him by the Duke of Cambridge, and the gold watch presented to him by his Excellency Prince Malcolm Khan, the Persian Ambassador, to such of his sons as his wife thinks most deserving.

The following legacies have recently been left to hospitals and other medical charities:—Mrs. Elizabeth Ann Forest, late of Uplands, Winchester, £100 each to the Brompton Cancer Hospital, the West Kent County Hospital, and the Royal Hants County Hospital.—Mr. Benaiah Gibb the younger, late of 1, Dartmouth Villas, Lewisham, £100 to the Seamen's Hospital, Greenwich.—Mr. James Bigwood, of Bristol, £100 each to the Royal Infirmary, General Hospital, and Children's Hospital, Bristol.

THE Cottage Hospital which has been erected at Burslem in connexion with the Haywood Charity was opened on the 20th inst.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 5799 births and 3252 deaths were registered during the week ending June 18th. The annual rate of mortality in these towns, which had been 20·4, 19·5, and 18·9 per 1000 in the preceding three weeks, further declined last week to 18·4, and was lower than in any preceding week of this year. During the first eleven weeks of the current quarter the death-rate in these towns averaged 20·1 per 1000, and was 1·5 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 12·2 in Derby, 13·4 in Birmingham, 13·8 in Halifax, and 14·1 in Norwich. The rates in the other towns ranged upwards to 24·3 in Huddersfield, 25·0 in Blackburn, 26·2 in Newcastle-on-Tyne, and 28·5 in Manchester. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had declined in the preceding four weeks from 532 to 489, were last week 501; they included 226 from measles, 132 from whooping-cough, 41 from scarlet fever, 49 from diarrhœa, 26 from diphtheria, 27 from "fever" (principally enteric), and not one from small-pox. No death from any of these zymotic diseases was registered during the week in Wolverhampton; while they caused the greatest mortality in Brighton, Blackburn, Birkenhead, and Manchester. The highest death-rates from measles occurred in Sheffield, Oldham, Salford, Norwich, Brighton, Manchester, and Birkenhead; from whooping-cough in Plymouth, Bradford, and Nottingham; and from scarlet fever in Blackburn. The 26 deaths from diphtheria in the twenty-eight towns included 16 in London and 2 in Huddersfield. Small-pox caused no death either in Greater London or in any of the twenty-seven large provincial towns. Only two cases of small-pox were under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease; one new case was admitted to these hospitals during the week. The deaths referred to diseases of the respiratory organs in London, which had been 333, 264, and 259 in the preceding three weeks, further declined last week to 213, and were 23 below the corrected weekly average. The causes of 78, or 2·4 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Birmingham, Bristol, Sunderland, Nottingham, and in three other smaller towns. The largest proportions of uncertified deaths were registered in Huddersfield, Halifax, Salford, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·8 and 21·9 per 1000 in the preceding two weeks, declined again to 19·3 in the week ending June 18th; this rate exceeded, however, by 0·9 the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 9·7 and 12·4 in Perth and Aberdeen, to 22·2 in Paisley and 23·0 in Dundee. The 483 deaths in the eight towns last week showed a decline of 63 from the number in the previous week, and included 48 which were referred to whooping-cough, 13 to measles, 10 to scarlet fever, 10 to diarrhœa, 5 to "fever" (typhus, enteric, or simple), 4 to diphtheria, and not one to small-pox; in all, 90 deaths resulted from these principal zymotic diseases, against 50 and 76 in the preceding two weeks. These 90 deaths were equal to an annual rate of 3·6 per 1000, which was 0·7 above the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 32 and 35 in the preceding two weeks, further rose last week to 48, and included 16 in Glasgow, 14 in Dundee, 8 in Edinburgh, 4 in Greenock, and 4 in Leith. The deaths from measles and scarlet fever also exceeded the numbers in recent weeks; measles caused 11 deaths in Glasgow, and scarlet fever 6 in Glasgow and 3 in Dundee. The 10 deaths attributed to diarrhœa showed a decline of 2 from the number in the previous week, but exceeded those returned in the corresponding week of last year by 2. Of the 5 deaths referred to "fever," 3 occurred in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 102 and 109 in the preceding two weeks, declined last week to 76, and was 17 below the number returned in the corresponding week of last year. The causes of 76, or nearly 16 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 21·4 and 31·2 per 1000 in the preceding two weeks, declined again to 26·7 in the week ending June 18th. During the first eleven weeks of the current quarter the death-rate in the city averaged 28·8 per 1000, the mean rate during the same period being but 18·3 in London and 19·6 in Edinburgh. The 181 deaths in Dublin last week showed a decline of 30 from the number returned in the previous week; they included 18 which were referred to measles, 6 to scarlet fever, 5 to "fever" (typhus, enteric, or simple), 3 to whooping-cough, and not one either to small-pox, diphtheria, or diarrhœa. Thus the deaths resulting from these principal zymotic diseases, which had been 21 and 29 in the preceding two weeks, further rose last week to 32, and exceeded the number in any previous week of this year; they were equal to an annual rate of 4·7 per 1000, the rates from the same diseases being 2·9 in London and 1·8 in Edinburgh. The fatal cases of measles, which had been 17, 10, and 18 in the preceding three weeks, were again 18 last week. The deaths from scarlet fever and "fever" showed an increase upon recent weekly numbers. The deaths both of infants and of elderly persons were fewer than those returned in the previous week. Two inquest cases and 2 deaths from violence were registered; and 57, or nearly a third, of the deaths occurred in public institutions. The causes of 24, or more than 13 per cent., of the deaths registered during the week were not certified.

Correspondence.

"Audi alteram partem."

"THE DOCTOR'S INCOME."

To the Editors of THE LANCET.

SIRS,—Dr. Paget Thurstan is doubtless right in saying that his letters on the income of doctors have excited much interest. It is surely interesting, though not encouraging, to learn how poor we most of us are, and how unequal is the distribution of what wealth there is amongst us. What strikes me as of chiefest interest, however, in his letters and in other communications from other pens, is the tacit assumption that the hospital doctor is largely and mainly answerable for all the woes and the poverty of his non-hospital brethren. And yet not a tacit assumption only, for after detailing the case of a patient who ultimately reached a hospital, where she was treated for nothing, and then died, her whole medical expenses throughout a long illness having amounted to *five shillings*, he says: "But the system which *makes* the hospital doctor *breaks* hundreds of his less fortunate brethren." If the hospital doctor is *made* in the country by his hospital connexion—*made*, that is, both as to professional status and pecuniary comfort—and we will not deny that it is a vast help to him towards success in life,—it is far different with his hospital brother in London. The hospital doctor in London may derive a certain position from his hospital appointment, but no greater delusion exists than that it is the means of bringing him professional income. I doubt if the profession has the shadow of a notion as to the pecuniary difficulties which beset many a hospital doctor in London. Doomed for years, it may be, to the monotony of out-patient practice, by which he is supposed to be qualifying himself for the treatment of in-patients in the remote future, and, so far, too inexperienced for consulting work, forbidden by custom to earn a living by general practice, and compelled to have a respectable house in a respectable quarter—Harley-street or Brook-street, for example—that he may look, at any rate, as if he were a prosperous man, it is neither more nor less than the truth that, unless by some lucky chance or other he has an independent income to maintain himself, has a lucrative appointment, or a wife with a dowry, has property of his own, or enjoys an allowance from his parents, he has to pass the best years of his life—perhaps his whole life—oppressed by the load of pecuniary want. The public has little idea that the doctors alone of the staffs of the hospitals

Digitized by Google

do their work without remuneration or reward, and general practitioners are many of them so slow to seek or encourage consultative advice that true *consultations* are extremely rare. Hence it happens that, with a few solitary exceptions, the men who thrive pecuniarily and are satisfied are those who know best how to appeal to the public, and who best cultivate the art of advertising themselves, even though it be at the risk of some distrust on the part of their own brethren. The profession does not hear much of this side of hospital doctors' lives in London, for where is the man who will openly tell you that he is not getting on, or who will boldly admit that he has not taken a single fee for many months? Could the truth be told, the profession would stand amazed at the insignificance of the purely professional incomes of hospital doctors here in London, and at the utter inadequacy of their incomes, even for the bare necessaries of life. Cutting sections and showing fragments of your departed patients at the Pathological Society may do much for scientific progress: neither pastime does much for bringing in the means of living. When, therefore, Dr. Paget Thurstan and others write and speak of a system which *makes* the hospital doctor and *breaks* his less fortunate brethren, they do so in ignorance of the real pecuniary condition of one important branch of the profession, the so-called pure consultants in London, supposed to be ever flourishing on the plethora of their guinea or two guinea fees. No, it is not the hospital doctors who *break* the general practitioner; and if the general practitioner desires to raise his income, let him look for and find the means of improving it nearer home. If combination be necessary towards this end, by all means combine; but, above all, do away with the practice of underselling each other, which cannot be otherwise than harmful to the whole profession. Let it not be forgotten, moreover, that the system of *hard work and no pay* which prevails in this rich metropolis amongst hospital doctors demands as much reform as the system of "hard work and poor pay" against which Dr. Paget Thurstan has raised his voice. "Consultants," he says, "are to family doctors almost precisely as barristers are to solicitors." There is much aptitude in this comparison. The briefless barristers who swarm in the law courts have their exact counterpart in the feeless consultants who herd together and who look so cheery and contented in the regions round about Cavendish-square.

I am, Sirs, yours truly,

June 15th, 1887. A HOSPITAL SURGEON.

To the Editors of THE LANCET.

SIRS,—Dr. Paget Thurstan has sent you a letter, very valuable in pointing out some great abuses, but ending in so miserable and hopeless a manner that it becomes simply a jeremiad. To me the very blackness of the present condition of general practice is the most hopeful of signs. It is always darkest just before the dawn, and it is the monstrous nature of the abuses to which we are subject which will infuse energy and method into the amœboid mass of general practitioners, and show that they have both brains and mouths, not to mention pens. The most powerful agent at our command is the press, and I believe we shall always find the medical journals more especially willing to aid us in gaining proper respect for the position and remuneration for the services of the medical practitioner. We must have *combination*. *Cela va sans dire.* We do not require a trades' union which shall fetter individual discretion, but combination to protect us from the encroachment of gratuitous treatment and the contract system as applied to people able to pay ordinary fees. That is the question in a nutshell. Hospitals, clubs (including friendly societies' associations), and dispensaries, free or provident, must be regulated in the interests both of the general public and the profession. The Council and Corporations will do for us absolutely nothing unless by means of pressure from without. Like Coriolanus, "alone we must do it," but "alone" for us means an army of over 10,000. We want leaders in this reform, and you, Sirs, with your influential organ, which can both form and lead the opinion of the profession, ought to be our leaders. Free us from the nightmare of the clubs and hospitals, and we can protect ourselves. Dr. Thurstan says the upper and middle classes pay fairly. Some of them do—some of them are club patients. It ought not to be possible that they can obtain medical advice for a shilling a quarter.

The chief requisite reforms seem to be:—1. That [illegible] mission committees shall investigate the circumstances of all patients receiving gratuitous advice, or semi-gratuitous advice, by means of provident dispensaries, clubs, and friendly societies' associations. 2. That a certain scale shall be fixed from time to time to guide these committees in the exercise of their duties. 3. That amongst the working-classes the ready-money system should be encouraged by a system of small fees. 4. That provident dispensaries should be instituted over the whole country by a national movement for the poor of the working class. 5. That for parish appointments some uniform system of payment should be provided.

I cannot agree with Dr. Thurstan as to payment by shilling fees for paupers. It would involve a heavy burden upon the ratepayers in populous districts. Parish patients are (or ought to be) destitute, as far as means of procuring medical advice is concerned; and if it be necessary to provide for the class above them by provident dispensaries, it would be palpably unfair to tax the local rates with fees for their attendance which would be in excess of the average obtained from the provident patients.

If the above five reforms were insisted on, the medical profession would become more honourable and unselfish in its internal dealings, as well as in its relation to the public. THE LANCET has the power of passing these or similar measures by bringing the subject persistently and repeatedly before the profession and the public, and to THE LANCET I trust chiefly to accomplish this very desirable result.

I am, Sirs, yours truly,

J. B. PIKE,

May 23rd, 1887. Med. Officer, Loughborough District and Workhouse.

REFERENCE CASES UNDER THE SALE OF FOOD ACT.

To the Editors of THE LANCET.

SIRS,—Suppose a man to be accused of rape, and the medical examination of the woman to have been made promptly. Suppose in the course of some weeks the case to have come before the court, and the medical man who made the examination to state his decided opinion that a rape had been committed. Then suppose some doubt to be raised as to the accuracy of his opinion, and that the court in consequence order an examination of the woman by some higher authority. Suppose the referee were subsequently to come into court and state that he "could not affirm that the rape had been committed," and declined to give any further explanation. Would not the whole of the medical profession be up in arms against such evidence as one-sided, and calculated to frustrate the ends of justice? Why could not the referee state that, owing to the length of time which had elapsed since the crime was alleged to have been committed, his examination was worthless for the intended purpose, and that he could not form an opinion worth having, either one way or the other?

Now I will ask you in the light of this parable to read the following condensation of the complaint formulated in my letter to the *St. James's Gazette*, on which you comment in an article in THE LANCET of the 11th inst.

The Somerset House chemists who are appointed referees under the Act are placed in a very disagreeable and invidious position. Thus they are required to certify whether the condemnation of a sample by a public analyst was correct, when it very frequently happens that they are not in a position to certify either one way or the other; but instead of stating this, the wording of their certificates has commonly been that they were "unable to affirm that the sample in question was adulterated," thus leaving the magistrates to imagine that they affirmed it to be *un*adulterated, whereas the fact has been that from decomposition or other circumstances they could form no positive opinion on the matter. That this is frequently the case is evident from the fact that it has often been five or six weeks before the sample in dispute has reached their hands. Naturally, under such circumstances, no reliable analysis of the milk has been possible, and although the referees have attempted to avoid the difficulty by making an allowance for change in the milk according to the number of days it has been kept, it is evident that without a knowledge of the circumstances and temperature under which it has been preserved any such corrections are of a wholly worthless character. I may point out also, with every

Digitized by Google

personal respect for the Somerset House chemists, that the assumption that they are bound to give the benefit of any doubt to the defendant is not in accordance with their position as impartial referees. It is their duty to state fairly the result of their analysis, and whether from it they believe the milk to have been adulterated. If they cannot speak with certainty, they might speak of probabilities, and if they cannot make up their minds at all they should say so, and leave the course of giving the benefit of any doubt to the court in the usual manner, and not exercise the prerogative of mercy themselves. I would further point out that the example of testing for arsenic is by no means a fair parallel with that of examining milk for water. It is not the *analysis* that is the actual determination of the constituents of the milk which is difficult, but the *interpretation* of those results, with due regard to the variable composition of natural milk, and to the fact that the rate of decomposition of milk by keeping is extremely variable. If arsenic were a body liable to a certain range of variation in its characters, and liable to considerable change by keeping, a toxicologist might be quite justified in saying that he was not certain if there had been arsenic originally present, but he thought it probable. The toxicologist might with advantage add that his opinion under the circumstances was necessarily of very little value as compared with that of the man who had examined the material under much more favourable conditions. No one suggests that the Somerset House chemists should certify that a sample was adulterated unless their own analysis proved the adulteration. My contention is that when, from decomposition or other circumstances, they know their analysis to be worthless they should state so candidly, instead of contenting themselves with the statement that they are "unable to affirm the fact of adulteration." The fact is that it is unfair to the Somerset House chemists to place them in such a position. The remedy is a simple one, and consists in adopting the plan which has been in use with great success for several years past in Derbyshire, for the southern division of which county Mr. Otto Hehner is the analyst, while I am the similar officer for the northern division. In the case of either of us having a sample of milk believed to be adulterated, he sends it without delay to the other, who also gives a certificate on it, so that there are two independent analyses made of the fresh, or nearly fresh, milk. This course practically precludes all chance of error on the part of the analyst, and is a far more satisfactory way of checking him than by sending the milk to Somerset House when five or six weeks old, and when, therefore, it is quite impossible to make any trustworthy analysis of the sample.

I am, Sirs, yours truly,

ALFRED H. ALLEN, F.I.C., F.C.S.,
President of the Society of Public Analysts.

Sheffield, June 13th, 1887.

THE IRISH MEDICAL ASSOCIATION AND THE PRACTICAL ELEMENT IN MEDICAL EDUCATION.

To the Editors of THE LANCET.

SIRS,—The annual meeting of the above body was held the other day, and though I previously invited the secretary, Dr. Chapman, to refer to the various matters of interest to provincials which I have ventilated in your columns and in those of the medical press during the year, yet no reference whatever was made in their report to them. I trust to be able to attend the annual meeting of that body next year, and I will then and there raise the question of grievances which it is the interest of the metropolitan knot who at present pull all the wires in that association to stifle. I was very much struck the other day with a remark of Montesquieu, to the effect that the father who gives his art to his children has left them a fortune. Now this is what the physicians and surgeons of former generations were able to do, and what numbers of nearly every calling of the present day (our own excepted) can do. Metropolitan folk, by abolishing apprenticeship, have contrived to make us an exception to every other class in the community. It now costs us as much to induct our sons into the profession as if their fathers were the veriest strangers to it. I hope that the approaching meeting in Dublin will witness the establishment in Ireland of a branch of the English General Practitioners' Association.

The mouse which the committee of the General Medical Council on the practical element in medical training brought forth as the result of the labours of the mountain is an insult to common sense and to the whole of us, and the public have a right to ask for a strict account of the part taken on that occasion by each of its elected representatives.

I am, Sirs, yours truly,

THOMAS LAFFAN.

June, 1887.

*** Mr. Laffan writes as if the Council had disposed of the "practical-element-in-medical-education" question, which is quite a mistake. The report of the committee is still *sub judice*, and has been referred to an Education committee. And that report contains the nucleus of most important suggestions with regard to pupilage, an improved midwifery course, and more attention to practical subjects and common diseases in the final examinations.—ED. L.

"A SUGGESTED IMPROVEMENT IN ETHER INHALERS."

To the Editors of THE LANCET.

SIRS,—I think that most anæsthetists who have read the recent letters in your journal under the above heading will agree with the criticisms passed on that class of ether inhalers in which a bag for the inhalation of a mixed atmosphere of ether and the products of respiration is an essential part of the apparatus. With the view of inducing anæsthesia by the inhalation of ether unmixed with respiratory products, I designed some years ago a simple apparatus, a description of which appeared in your columns on July 5th, 1884. Continued experience with this inhaler fully endorses the remarks made on that occasion, and I have only to add that the patient does not foul the instrument, and that it is always ready for use. It was constructed for me by Messrs. Krohne and Sesemann, London.

I am, Sirs, yours truly,

P. BLAIKIE SMITH, M.D.,
Physician, late Anæsthetist, Aberdeen Royal Infirmary.

June 16th, 1887.

LIVERPOOL.

(From our own Correspondent.)

MEASLES EPIDEMIC.

THE medical officer of health reports that the epidemic of measles, which has been prevalent for the past three or four months, is now subsiding. The number of new cases reported daily by the school officers has undergone a more marked diminution than the recorded deaths, which during the last eight weeks have been as follows:—

April 23rd	...	49 deaths.	May 21st	...	25 deaths.
„ 30th	...	39 „	„ 28th	...	15 „
May 7th	...	38 „	June 4th	...	25 „
„ 14th	...	30 „	„ 11th	...	17 „

The deaths are still considerably above the average. Dr. Taylor has repeatedly urged the necessity for the provision of hospital accommodation if threatening epidemics are to be grappled with, and it is sincerely to be hoped that the city council will give the matter their careful consideration.

THE WEATHER.

The change from the almost wintry weather which prevailed here during the last month to the intense heat of this month has been most remarkable, and in some instances has been attended with serious results, several cases of sunstroke having occurred.

BURIAL REFORM.

A meeting of the Church of England Burial, Funeral, and Mourning Reform Association was held here on the 7th inst. The Lord Bishop of the diocese presided, and advocated the use of perishable coffins and simple burial in the earth. Mr. Clarke Aspinall, the city coroner, who seconded the first resolution, defended burial clubs as a prudent provision, without which there might otherwise be frequently very serious difficulties; but he deprecated the popular idea that the whole of the club money should be spent upon the funeral. Mr. F. W. Lowndes, who seconded the second

Digitized by Google

resolution, condemned the practice of washing the body, as also that of standing bareheaded at funerals, urging that the health of the living must always be preferred to any wish to do honour to the dead.

ALLEGED TRIPLE MURDER BY A MOTHER.

A woman has been committed for trial for the murder of her three children, a son and two daughters. The boy was taken to the Stanley Hospital, where Dr. Arthur Wood, the resident surgeon, found him suffering from a gaping wound in the throat about four inches long and two inches broad; the windpipe was nearly severed, being cut in two places. A silver tracheotomy tube was inserted, and the child lived for sixteen hours, subsequently dying from hæmorrhage. The pupils of the eyes were strongly contracted. The two other children were seen at their own home by Dr. Robert Gordon, who found them both dead on his arrival. One of them had a wound almost three inches in length, extending to within an inch of the left ear and half an inch of the top of the breast bone. The windpipe was half divided between the second and third rings. The left internal jugular vein was also severed. The other child had apparently died from suffocation. It was shown in evidence that the prisoner had sent a girl eleven years old for twopennyworth of laudanum, which had been supplied. The magistrate remarked that the Poisons Act required amendment. When arrested, the prisoner admitted having given the children laudanum to quiet them.

THE LATE DR. OXLEY.

The remains of this much-lamented gentleman, whose death occurred at Llandudno on the 14th inst., as noticed in last week's LANCET, were brought home for interment in St. James's Cemetery, which is within a very short distance of the house where the deceased resided. The funeral was of a very simple character, the body being carried on a hand bier to the cemetery and buried in a grave. It was largely attended by his medical brethren—some from a considerable distance—as well as a number of friends, with all of whom the deceased was extremely popular. Though so young, being only in his forty-seventh year, he had suffered from heart disease more or less for some years past, and could probably have only lived to suffer even more than he had. He will be greatly missed.

JUBILEE CELEBRATION AT THE ROYAL SOUTHERN HOSPITAL.

A special service was held in the chapel of the Royal Southern Hospital at 10.30 A.M. to-day, when jubilee hymns were sung, and a short address was delivered by the chaplain. After this, a distribution of medals took place to the number of nearly 350, each medal being attached to a blue ribbon, stamped with the name of the hospital and the date. A band of music was stationed on the bridge commanding the two wings of the hospital, and all the inmates of the hospital who were sufficiently convalescent, together with the medical and nursing staff, and some visitors, were present while a programme of music was excellently performed. Oranges and other refreshments were provided for the patients, as well as an extra good dinner.

BEQUESTS TO HOSPITALS.

Under the will of the late Mr. John Bacon (late of Liverpool and of Clwyd Hall, Llanyelian, Denbighshire), shipowner, the following medical charities receive £1000 each: Liverpool Royal Infirmary, Northern Hospital, Royal Southern Hospital, Stanley Hospital, Bootle Borough Hospital, and Denbigh Infirmary. The Convalescent Institution, Woolton, near Liverpool, receives £300.

JUBILEE DAY AT THE LIVERPOOL NORTHERN HOSPITAL.

The patients at the Liverpool Northern Hospital were entertained with a cheering repast, and each was presented with a medal, the gifts of two ladies, Mrs. Harmood Banner and Miss Johnson. The male patients were permitted to smoke, pipes and tobacco being given them. A concert was given in the evening, Dr. Fisher presiding at the piano, assisted by Drs. Thomson, Servaes, Haswell, and Ross.

Liverpool, June 21st.

ON the 19th inst. the eleventh annual demonstration of the friendly societies in aid of the funds of the medical charities of the borough was held at Middlesborough.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

ILLNESS ON BOARD THE CHINESE TRANSPORT "TOO NAN"

SOME uneasiness in the public mind here was lately caused by the report of serious illness on board the Chinese transport *Too Nan*, now lying in the Tyne. The vessel had only been a day or so in the river when two of the crew, which numbers nearly 700, became so seriously ill that they had to be removed to the Newcastle Infirmary, where they died soon after their arrival; a third died on board before he could be removed. It appears also that two of the crew died at sea on the voyage to the Tyne. Dr. Slater of this city has been called in to attend the sick on board, and he found as many as fourteen suffering from that obscure Oriental disease known as beri-beri or kakkè. Like most other general diseases, beri-beri appears to assume an acute and chronic form. In the former, there are general anæmia and dropsy, severe pain over the cardiac region and a feeble tottering gait, with speedy death, either from syncope or from blood-clots in the right side of the heart or pulmonary artery. In the mild or chronic form recovery is frequent, and Dr. Slater's present cases fortunately belong to this class. The treatment, as might be expected from the symptoms, consists in stimulants, iron and quinine, with nourishing diet; but it is to be hoped that Dr. Slater will send you a detailed account of this outbreak of a curious disease, so rarely observed in European ports.

SUNDERLAND.

As a result of the representations of an influential deputation which waited on the Ecclesiastical Commissioners last week relative to the new Hartley wing of the Sunderland Infirmary, the Commissioners have decided to increase their donation from £250 to £500. Mr. A. E. Harris, medical officer of health, writes to say that the registered deaths for Sunderland last week were 37, and not 57, as stated in mistake in the Registrar-General's returns, which brings out the death-rate as 14·9, and not 22·9, as published in the official returns. Some interesting vaccination returns have been published for Sunderland, which show that the total number of births for the past year had been 5603; of these 4929 had been successfully vaccinated, 488 died before vaccination, 55 were postponed on medical authority, and 128 had removed to other parishes, which had been communicated with by the vaccination officer. Only three cases of the whole had not been vaccinated, and the parents of these had been summoned.

MEASLES IN NORTHUMBERLAND AND DURHAM.

Dr. Duncan, medical officer of health for Chester-le-Street, says that the outbreak of measles at Birtley is the worst that has occurred at the union for many years. A large number of deaths have taken place at Birtley and Portobello, and the officer had personal knowledge of over 300 cases. At Jarrow, too, the disease has been rife, and has become a subject of discussion in the Town Council. At Killingworth and Morpeth the disease continues. Newcastle and Gateshead are comparatively free, but fears are expressed that the coming jubilee festivities may give rise to a recrudescence of the disease.

Newcastle-on-Tyne, June 20th.

EDINBURGH.

(From our own Correspondent.)

PROFESSIONAL COMPLIMENT TO DR. HERBERT ASHDOWN

ON the 16th inst. Dr. Herbert Ashdown was entertained at a complimentary dinner and presented with an address by his professional brethren in this city. The occasion chosen was that of his departure on a visit to Canada, there being a strong feeling that this juncture offered an appropriate opportunity for expressing the wide-felt sympathy awakened by the difficult and painful position which he has recently been compelled to occupy through no fault of his own. Between forty and fifty gentlemen attended the dinner, which was presided over by Dr. George A. Gibson.

Digitized by Google

Secretary of the Royal College of Physicians, and the proceedings were throughout of the most enthusiastic character. Numerous apologies for absence were intimated from prominent members of the Edinburgh School, expressing sympathy with the object of the meeting. In proposing the toast of the evening the chairman referred to the warm esteem in which Dr. Ashdown is regarded, and to the faithful and efficient services he has rendered in the University Medical School. Throughout a long career in Edinburgh he had comported himself with the dignity and integrity of a Christian gentleman, and should he at a future period return amongst us he might depend on all the sympathy and support that warm hearts and strong hands can give. He then presented the address, which was read by Mr. C. W. Cathcart, and is as follows:—"To Herbert H. Ashdown, Esq., M.B., F.R.S.E., late Senior Demonstrator of Physiology, University of Edinburgh. We, the undersigned, members of the medical profession in Edinburgh and of the teaching staff in the University, desire to take this opportunity of testifying to the high esteem in which you are held amongst us, and our sympathy with you in the difficult position which recent circumstances have compelled you to occupy. Your brilliant career as a student, and your success as a teacher, both of anatomy and physiology, in the University of Edinburgh have earned for you the respect of all with whom you have been brought in contact, while your high scientific attainments have been recognised by a wider circle of fellow-workers. Your published writings have reflected credit on the school with which you have been long and honourably connected. Personally, your geniality of disposition, your sympathetic nature, your devotion to duty, and your stainless character have attached to you in close friendship a large number of the best men among your contemporaries. The feelings they entertain towards you afford the strongest testimony to your worth. In conclusion, we heartily assure you of our constant interest in your welfare. We anticipate for you a bright future, and feel certain that this is guaranteed by the possession of those qualities which have already gained for you so distinguished and honourable a place." This address was signed by ninety-eight names, representing all phases of professional interest in Edinburgh, and a number of additional names have since been appended. The address is handsomely engrossed on vellum. Dr. Ashdown accepted the gift amidst enthusiastic applause, and replied to the compliment in very cordial terms. The toast list included "The University of Edinburgh" and "The Edinburgh Medical School," the whole proceedings being of the most harmonious and congenial nature.

THE CONTAGIUM OF SCARLET FEVER.

At the last meeting of the Edinburgh Medico-Chirurgical Society specimens of the organism discovered by Dr. Edington in scarlet fever were demonstrated under the microscope. On the proposition of Professor Chiene, a commission was appointed to inquire into the results of Dr. Edington's research, and to bring a report to the Society at its special meeting next month, when the subject of scarlatina is to be discussed. The following gentlemen were appointed members of the Committee:—Prof. Grainger Stewart (convener), Prof. Greenfield, Drs. Carmichael, Philip, and Woodhead, and Mr. Hare. It is hoped that they will be in a position to give some opinion on the subject at the meeting which is fixed for July 20th.

RESEARCH SCHOLARSHIP.

Dr. William Hunter, F.R.S.E., has been appointed to the John Lucas Walker Scholarship in Experimental Pathology in the University of Cambridge. Much regret is felt in Edinburgh at the loss of this careful and successful observer, whose work on the blood has won him an honourable position among physiologists and pathologists. It is hoped, however, that his transference from this school to that of Cambridge may not be of a permanent character, but that the credit he is certain to reflect on his *alma mater* may in the future be associated with work done on her native soil.

THE JUBILEE CELEBRATIONS.

The 21st of June was observed as a University holiday. In the evening the students assisted in adding to the picturesqueness of the civic illuminations by holding a torchlight procession. About 600 torchbearers mustered in the University Quadrangle at 10.30 A.M., and traversed many of the chief streets of the city. Enormous crowds filled the streets, and collected on the various eminences in the city to watch the beacon fires which flashed out from the hills on all sides. No casualties are reported.

Edinburgh, June 22nd.

ABERDEEN.

(From our own Correspondent.)

THE ROYAL INFIRMARY.

THE quarterly meeting of the managers of the Aberdeen Royal Infirmary was held on Monday, the 13th inst., when the Lord Provost, who presided, intimated that the Jubilee Fund for the extension and reconstruction of the infirmary amounted to nearly £23,500. It was therefore resolved to proceed as soon as possible with the erection of the west pavilion, in which there is to be accommodation for 108 surgical cases, 12 beds for eye diseases, 13 for "lock patients," and 7 for diseases of women. The east pavilion is to be built afterwards, and is to be the medical side of the hospital, affording accommodation for 84 medical cases and 8 beds for cases of erysipelas. When the new buildings are completed there will be 233 beds, the space allowed for each being 90 superficial feet and 1400 cubic feet.

At the same meeting it was resolved to appoint a third resident medical officer, and to give each of the residents a honorarium of £25 a year. Professor Hamilton was appointed pathologist to the institution, and permission was given him to appoint a duly qualified practitioner to act as his assistant.

HEALTH OF THE CITY.

The measles epidemic has played itself out, and although there are several cases of scarlet fever and a few of typhus, still the health of the city, as compared with what it has been for a few months, may be considered satisfactory. The death-rate has fallen from 37·5 in March to 19·08 at present. Unfortunately, however, we are threatened with an outbreak of small-pox. The first individual affected is said to have been a ragworker, and it seems some time elapsed before the true nature of the disease was detected, and in a short time fourteen individuals became affected. They have all been removed to the city hospital, and it is to be hoped that the prompt means taken to isolate the cases will prevent the disease becoming epidemic. One of the town councillors at their meeting yesterday, when this threatened epidemic was under consideration, made the extraordinary statement "that there were four or five medical men in Aberdeen who did everything they possibly could to thwart the sanitary officials, refusing or delaying to report cases of zymotic disease until such time as an outbreak like the present occurred!"

Aberdeen, June 21st.

DUBLIN.

(From our own Correspondent.)

UNIVERSITY OF DUBLIN.

AT the annual meeting of the Senate, to be held on Wednesday, June 22nd, the following graces from the Provost and Senior Fellows will be submitted: That the degree of Doctor of Medicine be conferred (*honoris causâ*) upon William Tennant Gairdner of Glasgow; Sir James Paget, Bart., F.R.S.; Sir Thomas Spencer Wells, Bart., M.D.; Sir John Simon, K.C.B.; and Edward Waters, M.D. That the degree of Doctor *utriusque juris* be conferred (*honoris causâ*) upon His Royal Highness Prince Albert Victor Christian Edward of Wales.

THE QUEEN'S JUBILEE.

The executive committee of the Queen's Jubilee Memorials Association have decided to make a considerable grant to the Hospital for Incurables, in aid of the establishment of the new wing for the treatment of patients suffering from cancer and consumption. This arrangement, it is to be feared, will do away with the erection of the Hospital for Consumption and other Chest Affections which it was suggested should be established at Killiney, and which is so

Digitized by Google

urgently needed. His Royal Highness Prince Albert Victor will formally open the Royal Jubilee Wards in the National Children's Hospital, Dublin, on Wednesday, the 29th inst.

ROYAL COLLEGE OF SURGEONS: BEQUEST BY THE LATE DR. JOHN BARKER.

The College of Surgeons has had a sum of more than £1000 transferred to its credit, being a legacy by the late Dr. John Barker, formerly a Curator and Examiner of the College. Dr. Barker wished the money to be expended in prizes for the best dissections sent in by medical students, the prize to be awarded by the Curator of the College, the President, and the Professor of Anatomy in the University of Dublin. The sum of £10 was to be given to the Curator to entertain, in the College if possible, the successful student. Counsel's opinion was obtained as to whether this money could be utilised for general College purposes or for prizes for dissections, and as a result the Council were informed that they should follow the directions of the testator's will, unless they could not be carried out.

CORK-STREET FEVER HOSPITAL.

From the eighty-third annual report of this institution, I learn that of 709 cases treated in the hospital during the year, 59 died, or 10·31 per cent. Were it not for a prolonged epidemic of scarlatina existing in the city, the total number of zymotic diseases would have fallen far short of those treated during previous years. There were only sixty-two cases of typhus fever under treatment during the past year, a number below any previous record in the hospital. The mortality from scarlatina was only 8·72 per cent.

Deputy Surgeon-General R. Webb has taken over the duties of principal medical officer for the Dublin district.

The late Mr. Richard Kemmis has left £100 respectively to the Adelaide and Meath Hospitals, Dublin.

Dublin, June 21st.

BELFAST.

(From our own Correspondent.)

THE ULSTER MEDICAL SOCIETY.

AT a meeting of the members of this Society, held last week, it was decided, upon the motion of Professor Dill, seconded by Dr. Gibson, that an address be forwarded to Her Majesty the Queen on the occasion of her Jubilee. The address was then adopted, in which attention is drawn to the interesting fact that the Ulster Medical Society is one of the oldest medical organisations in Ireland, having witnessed Her Majesty's birth, coronation, and happy reign of half a century.

DEATH OF THE PRESIDENT OF THE ROYAL HOSPITAL.

I regret to have to announce the death of W. T. B. Lyons, D.L., President of the Board of Management of the Royal Hospital, which took place under exceptionally sad circumstances on May 4th. The deceased gentleman was suddenly seized with illness while presiding at the weekly meeting of the Hospital Board of Management. He was removed to the superintendent's room, and thence to his daughter's residence, where, a few hours after his sudden seizure, he succumbed, his death being due to cerebral hæmorrhage. Mr. Lyons was one of the warmest friends of the Royal Hospital, and as chairman of the Board of Management he always displayed great tact, judicial wisdom, and kindness. No one has as yet been appointed as his successor.

THE CHAIRMANSHIP OF THE PORTADOWN TOWN COMMISSIONERS.

At a special meeting of the Portadown Town Commissioners held last week Dr. George Dougan was re-elected chairman for the ensuing year, having already occupied that position for the past two years. Dr. Dougan had come to the meeting determined not to hold office any longer; but so unanimous and cordial was the request of his brother commissioners that he would again preside, that he ultimately acceded to their wish.

EPIDEMIC OF RÖTHELN.

During the past two months Belfast has been visited by a very widespread epidemic of German measles. The type of the disease, as a rule, has been mild, but adults have suffered much more when attacked than children. In some of the public schools its spreading has been much facilitated by the fact that parents have in some cases, from the mildness of the attack, allowed their children to go on attending classes. I have not heard of any fatal cases. The enlargement of the glands at the back of the neck has been a marked feature in the epidemic.

THE ULSTER EYE, EAR, AND THROAT HOSPITAL.

In the printed report of this hospital I find that Dr. McKeown gives a very interesting tabular statement of forty-nine cases of cataract for the year 1886. In all except three the new operation by injection was done, a method which was first introduced by Dr. McKeown in 1884, and which has the advantage that by it patients need not wait until the cataract is ripe, but can be operated upon more speedily and with greater ease and certainty than formerly. This is the second series of cases published by Dr. McKeown.

Belfast, June 21st.

PARIS.

(From our own Correspondent.)

PROPHYLAXIS OF SYPHILIS.

AT the two last meetings of the Academy of Medicine, Professor Fournier read the report of the commission appointed to inquire into this question, and the importance of the document may be understood from the fact that the first instalment takes up nearly thirty pages of the *Bulletin de l'Académie*. The best *résumé* of it is given by the *Gazette Hebdomadaire*, which sensibly moderates the eminent professor's somewhat undue raciness of description, at the same time weeding out some of the more questionable neologisms—e.g., to quote but a single example, such expressions as the hybrid "polymortality." This report is the basis of the propositions submitted by the commission to the Academy in order to be transmitted to the Government with the view of showing to what extent syphilis is a permanent danger to the public health, and what means should be taken to remedy this danger. The disease, says the reporter, is, indeed, disastrous and dangerous through its multiple consequences, individual, social, and hereditary. It is, with alcoholism, one of the gravest social evils of the present time. It is looked upon in society as the result of a series of successive contaminations rather than the consequence of a single contagion, and it is therefore supposed to be evidence of an ill-spent life of debauch. This view is erroneous. Syphilis is contagious, like all other contagious diseases—i.e., it results not from repeated infections, but from one alone. There are numbers of people who acquire the disease from what Professor Fournier terms "moral virtuous," or purely accidental, contagions, but syphilis, both deserved and undeserved, has a common origin. The infection of a virtuous wife and the contamination of a child may most often be traced back to disease of a prostitute; hence the consequence that to combat syphilis in the latter is to protect both the virtuous wife and child. Public interest requires that such an evil should be repressed by general measures capable of reaching it at its source. These measures are of three kinds: 1. The extension of the disease may be restrained by administrative or police regulations to prevent provocations in the public thoroughfares, by what is called the inscription or registration of prostitutes, which brings them under police and sanitary supervision, by the inspection of those establishments which, under the names of taverns and drinking bars, are in reality nothing else than houses of assignation. 2. Syphilis may be checked, in the second place, by treatment by hospitalisation—i.e., by extinguishing its germs of contagion. 3. It may be combated not less efficiently by teaching the rising medical generation more thoroughly than has hitherto been done all that concerns the symptom of this disease in its different forms, its social dangers, and its treatment. As regards measures of administrative prophylaxis, the Commission was unanimous in declaring that prostitution constitutes a public danger by the contagion which it disseminates in the population. It is therefore indispensable, both on hygienic and moral grounds, that it should be supervised, and, if necessary, repressed by the public authorities. The measures proposed for this purpose

Digitized by Google

by M. Fournier are briefly as follows: In the first place public provocation should be considered as a misdemeanour (*delit*). This measure, entirely in accordance with public opinion, would have the effect of removing habitual prostitutes from the arbitrary jurisdiction of the police. Those convicted of the offence should be *inscrites*, and subjected afterwards to periodical examination. Special hospitals for the treatment of venereal diseases should be created for the large centres of population, and the medical direction given to specialists, who should engage to remain in charge for at least five years; but in respect to the army, the Commission proposes that lectures on syphilis should be delivered to the soldiers to make them understand the dangers of contagion; that the men should never be punished for having contracted venereal disease; and that treatment should be continued after the soldier has returned to duty. Professor Fournier's final recommendation is for the benefit of society at large. Henceforth no wet nurse should be allowed to receive an infant without a medical certificate that the parents are free from syphilis.

LA SUETTE MILIAIRE.

The *Bulletin Medical* gives the following particulars concerning the epidemic mentioned in my last letter. Towards the end of April and the beginning of May an epidemic of measles of exceptional violence broke out in a little village of the arrondissement of Montmorillon, and during the first days of May the miliaria was seen at Montmorillon concurrently with measles. Under fifteen years of age all the deaths occurred from measles. Above that age the cause of death was always *la suette*. Measles and *suette* killed in two days at the outside, and the latter sometimes in a few hours. From Montmorillon the epidemic spread to the neighbouring villages, the order of invasion being always the same, measles in the children, miliaria in the adults, the first preceding the second chronologically. In the same house all the children would be attacked with measles, whether they had had it before or not, and the adults by the sweating disease. The measles was peculiar in that it always began by a sweat. In some instances the extension of the disease was more rapid than in others. In one place there were 63 pupils attending the school. The first day 26 of these were suffering from the disease; on the second, 38; on the third, 46; and on the fourth the school was closed. A short time afterwards the master had the *suette* and one of his children the measles. The symptoms of this pseudo-rubeola and of the *suette*, which are essentially the same disease, were as follows. The patient was generally seized suddenly at night or in the evening. A profuse sweat then occurred, "running down as if water had been poured on the head." At the same time a feeling of extreme anxiety, resembling angina pectoris, was complained of. The sweats and suffocations would return by paroxysms, and these symptoms would be accompanied by an eruption of sudamina. In fatal cases death took place by syncope, preceded by delirium and slowing of the pulse. After the first five days the worst was generally over, although even during convalescence there was still danger, death occurring occasionally at this period with strange nervous symptoms, such as anomalous pains, feelings of suffocation, irregularity of the pulse and of the cardiac contractions. Death was sometimes preceded and often followed by nasal and buccal hæmorrhages, and the post-mortem decomposition was very rapid. During convalescence there were polymorphous desquamations, resembling those of measles, scarlatina, and even psoriasis, sometimes with patches of purpura, and the patients remained for some time profoundly cachectic, with tremulation of the tongue and falling of the lips. The *suette* may be sporadic endemo-epidemic or pandemic, but it does not appear to be contagious, or, at all events, inoculable. Its miasma does not seem to be carried by the wind, the progress of the disease having been hitherto, in the Vienne, in the opposite direction.

Paris, June 21st.

LONGEVITY IN RUSSIA.—A woman named Sophia Masluchenóff has just died in Kharkoff at the age of 122. Up to the time of her death she enjoyed good health, and had an excellent memory.—A medical man practising at Novo Baiarzet writes to the *Vrach* that there is a peasant of the name of Mamed in the village of Beiok Mazra who is now about 122. He has good health and very fair eyesight. He is an exceedingly good walker. In his mouth are five sound teeth.

Obituary.

HENRY MILNE, M.D. ABER., &c.

DR. HENRY MILNE died on the 27th ult. at Bridge of Allan in his seventy-sixth year. In him passed away one of the finest specimens of a country surgeon and general practitioner that the north of Scotland has known during the last half-century. He was born in 1812, and came of a family that had been connected with Banff for about 300 years. Mr. John Milne, his father, had eleven sons, of whom nine grew to manhood, and to all of whom he gave a university education. Alumni of King's College, Aberdeen, Dr. Henry Milne and an elder brother took their whole medical curriculum at Edinburgh University under Abercrombie and Alison. After a voyage to India he took the degree of M.D. at King's College, Aberdeen, in 1833, and almost immediately succeeded to his brother's practice at Banff on his premature death. From that date till his retirement in 1861 his native district and county were the field of his ever-widening labours and success. His singular ability as a lithotomist and surgical operator very soon made itself known among his brethren and the public beyond his own county. The late Dr. Keith, the well-known lithotomist of Aberdeen, his contemporary, bore frequent testimony to his unrivalled skill, and had only one fault to find—that Dr. Milne would not publish his cases. Conducted as they were before the days of antiseptics, had he cared to do so, his would have been a proud boast that he had forty-two or forty-four consecutive cases of lithotomy without a death; and it must be remembered that many of these were undertaken in distant Highland glens and under conditions and surroundings that the operator of to-day knows nothing of. But it is the belief of those who remember him in his early days that this marvellous success and facility in resource were but a small portion of what struck his patients. There was a gentleness, a courtliness, and yet withal a quiet concentration about him that carried confidence and regard wherever he moved. To the few that knew him intimately he unbent freely, and showed a fund of humour and sly wit that at first was little suspected. The toilsome life he led slowly impaired a naturally healthy, but not vigorous, constitution. Gouty dyspepsia made itself known, and at last compelled him to retire at the early age of forty-nine. Dr. Milne married, in 1839, Miss Keith of Netherthird, and is survived by Mrs. Milne and their only child, a married daughter. He never mixed in public matters, though on one occasion pressed to accept the honour of the Provostship of Banff. For some time after his retirement he resided in the neighbourhood of this town, but in later years spent his life mainly at Bridge of Allan, Bournemouth, and Harrogate. His last years were passed in very precarious health, cardiac troubles rendering him much of an invalid and often a great sufferer; yet no weight of years or sickness ever dimmed the brightness of his intellect or narrowed his sympathies: true to the chief characteristics of his life, helpfulness and unselfishness. Even early and large success never spoiled the natural goodness of the man, for he was ever at the command of the poor man as well as the rich, and gave ungrudgingly.

JOHN PHILIP GLOVER, M.D. LOND.

DR. J. P. GLOVER was born at Derby on July 4th, 1846. At the age of sixteen he went to Australia, where he was engaged with a friend in hard and exciting work as a squatter until the great drought which caused the ruin of so many farmers. He then returned to England and entered the office of his uncle at Derby, where, by working alone and unaided in his spare moments, he qualified himself for passing the matriculation examination of the London University. After a year spent at the Derby Infirmary he entered St. Thomas's Hospital in 1879; he quickly passed his first college examination and preliminary scientific (in the first class), and gained distinction in the medical school. After he had obtained his diplomas at the Royal Colleges of Physicians and Surgeons, he was appointed house-surgeon to the Cheltenham Hospital, which appointment he held for twelve months. He then passed the M.B.Lond. examination

Digitized by Google

with honours in medicine. Afterwards he was house-surgeon to the West London Hospital, and then became a surgeon in the Orient Company's service for some months. Only last year he passed the M.D. Lond. examination, and showed no signs of the disease (tuberculosis) from which he died until about two months ago, when an attack of pleurisy developed, which was followed by symptoms indicating a general dissemination of the disease. Those who knew him well admired him very much not only for his cleverness, but also for his indomitable perseverance. He was a man of retiring disposition, and made few friends, but those were true, appreciating to the full his many merits.

JOHN TOPHAM, M.D. LOND.

OUR profession has lost an amiable and accomplished member by the death of Dr. Topham, whose life came to a close on June 17th, after a long and painful illness, endured with great fortitude and resignation.

Dr. Topham was a son of the late Rev. John Topham, for many years vicar of Droitwich. His professional education was received at University College, London, where he took a high place amongst the students, and secured many distinctions in the class competitions. He graduated in the University of London, taking the degree of M.B. in 1843, and gaining a scholarship in surgery at the examination for honours. He spent some time in Paris, took the degree of M.D. in London in 1846, settled in Wolverhampton, and was virtually the founder of the South Staffordshire Hospital in that town. A threatened development of lung disease in his wife compelled him to leave England, and he removed to Rome, where he resided and practised from 1860 to 1870. He was highly esteemed by and had many friends amongst the Anglo-American population of that city. Mrs. Topham's better health warranting his return to England, he took up his abode in Torquay, and lived there for some years; but for a considerable time his home has been in London. Endowed with an ample fortune, he gave up practice after his removal to town, and indulged his love for science and music. He was one of the most constant frequenters of the Royal Institution and of the concerts of the Philharmonic Society. He became an extra-Licentiate of the College of Physicians in 1848, a Member in 1861, and was elected to the Fellowship in 1880.

THE SERVICES.

WAR OFFICE.—Army Medical Staff: Surgeon Arthur Maher Kavanagh, from the seconded list, to be Surgeon (dated June 13th, 1887).

INDIA OFFICE.—The Queen has approved of the retirement from the service of the undermentioned officers of the Staff Corps and Indian Military Forces:—Brigade Surgeon Jas. Champion Penny, M.D., Bengal Medical Establishment (dated June 3rd, 1887); Brigade Surgeon John Cruickshank, M.D., Bombay Medical Establishment (dated April 1st, 1887); and Surgeon-Major George Moncrieff Govan, M.D., Bengal Medical Establishment (dated March 3rd, 1887). The undermentioned officers have been granted a step of honorary rank on retirement:—Brigade Surgeon John Cruickshank, M.D., of the Bombay Medical Establishment, to be Deputy Surgeon-General (dated April 1st, 1887); and Surgeon-Major George Moncrieff Govan, M.D., of the Bengal Medical Establishment, to be Brigade Surgeon (dated March 3rd, 1887).

ARTILLERY VOLUNTEERS.—2nd Northumberland (the Percy):—Adam Scott Purves, M.B., to be Acting Surgeon (dated June 18th, 1887).

RIFLE VOLUNTEERS.—3rd Cheshire: Surgeon Thomas Moreton is granted the honorary rank of Surgeon-Major (dated June 18th, 1887).—4th Volunteer Battalion, the Norfolk Regiment: Surgeon J. R. Clouting resigns his commission (dated June 18th, 1887).

UNDER the will of the late Mr. Fox, of Aberford, who died about a year ago, the treasurer of the Leeds Hospital for Women and Children has just received a legacy of £1000, and the treasurer of the Leeds Infirmary one of £5000.

THE memorial stone of the Merthyr General Hospital was laid on the 20th inst.

Medical News.

UNIVERSITY OF DURHAM FACULTY OF MEDICINE.—At the recent examinations for degrees in Medicine and Surgery the following candidates were approved:—

DEGREE OF DOCTOR IN MEDICINE FOR PRACTITIONERS OF FIFTEEN YEARS' STANDING.

Counsellor, William Parkinson, M.R.C.S., L.K.Q.C.P.I.
Goldie, Robert William, M.R.C.S. Eng., L.R.C.P. Edin.
Goude, Herbert, M.R.C.S., L.S.A., F.R.C.S. Edin.
Lloyd, Albert Eyton, M.R.C.S. Eng., L.R.C.P. Edin.

DEGREE OF DOCTOR IN MEDICINE (Essay)

Ainsley, Thomas George, M.B., M.R.C.S.
Bowden, Reginald Treacher, M.B., M.R.C.S., L.S.A.
Clowes, Herbert Alfred, M.B., M.S., L.R.C.P., M.R.C.S.
Hubbard, Arthur John, M.B., L.R.C.P., M.R.C.P.
Morgan, Llewellyn Arthur, M.B., M.R.C.S.
Willis, Charles Fancourt, M.B., M.R.C.S., L.R.C.P. Edin.

FINAL EXAMINATION FOR THE DEGREE OF BACHELOR IN MEDICINE.

SECOND CLASS HONOURS (IN ORDER OF MERIT).

Murray, G. Alfred Everitt, L.R.C.P., M.R.C.S., St. Barthol. Hosp.
Wholey, Thomas, L.R.C.P., M.R.C.S., L.S.A., London Hospital.

PASS LIST.

Bailes, Lewis Lamb, B.A., Coll. of Med., Newcastle-on-Tyne.
Baker, J. Barrington, M.R.C.S., L.R.C.P. Edin., Charing-cross Hospital.
Bird, Matthew Mitchell, St. Mary's Hospital.
Blight, William Lyne, L.R.C.P., M.R.C.S., Guy's Hospital.
Blurton, John Frederick, M.R.C.S., Queen's Coll., Birmingham.
Bootiman, John Smith, College of Medicine, Newcastle-on-Tyne.
Bredin, Howard Albert, M.R.C.S., L.S.A., Liverpool Roy. Infirm.
Brodrick, Harry Edw., M.R.C.S. L.S.A., Liverpool Roy. Infirm.
Close, John Borrill, M.R.C.S., L.S.A., St. Barthol. Hosp.
Edridge-Green, Frederic William, St. Barthol. Hosp.
Essery, William Joseph, King's College.
Evans, O. Conrad Penrhys, L.R.C.P., M.R.C.S., St. Barthol. Hosp.
Gibbon, Ernest Henry, Coll. of Med., Newcastle-on-Tyne.
Halsted, Harold Cecil, L.R.C.P., M.R.C.S., St. Barthol. Hosp.
Herring, Herbert Thomas, University Coll. Hosp.
Lodge, Samuel, Coll. of Med., Newcastle-on-Tyne, and Leeds Med. School.
Lund, Theodor, Coll. of Med., Newcastle-on-Tyne.
Metcalfe, George, Coll. of Med., Newcastle-on-Tyne.
Morton, Thomas, Coll. of Med., Newcastle-on-Tyne.
Nihill, John Edward, L.R.C.P., M.R.C.S., St. Barthol. Hosp.
Norton, John, Westminster Hospital.
Nott, Arthur Holbrook, L.R.C.P., M.R.C.S., Queen's Coll., Birm.
Pridmore, Walter George, M.R.C.S., Middlesex Hospital.
Robinson, Louis, M.R.C.S., L.S.A., St. Barthol. Hosp.
Steenberg, Charles William, Coll. of Med., Newcastle-on-Tyne.
Stokes, John, Coll. of Med., Newcastle-on-Tyne, and Sheffield Med. School.
Turtle, Frederick Wenman, M.R.C.S., Guy's Hospital.
Walker, Benjamin, M.R.C.S., L.S.A., London Hospital.
Watson, John, Westminster Hospital.
Wheeler, Humphry John, L.R.C.P., M.R.C.S., St. George's Hosp.
Wilbe, R. Haycock Wiffin, L.R.C.P., M.R.C.S., St. Barthol. Hosp.
Wilde, Leonard, St. Thomas's Hospital.

DEGREE OF MASTER IN SURGERY.

Openshaw, Thomas Horrocks, M.B., B.S., F.R.C.S., London Hosp.

DEGREE OF BACHELOR IN SURGERY.

Bird, Matthew Mitchell, St. Mary's Hospital.
Bredin, Howard Albert, M.R.C.S., L.S.A., Liverpool Roy. Infirm.
Edridge-Green, Frederic William, St. Barthol. Hosp.
Herring, Herbert Thomas, University College Hospital.
Lazenby, James Matthew, M.B. Coll. of Med., Newcastle-on-Tyne.
Lodge, Samuel, Coll. of M.d., Newcastle-on-Tyne, and Leeds Med. School.
Metcalfe, George, Coll. of Med., Newcastle-on-Tyne.
Nihill, John Edward, L.R.C.P., M.R.C.S., St. Barthol. Hosp.
Pridmore, Walter George, M.R.C.S., Middlesex Hospital.
Steenberg, Charles William, Coll. of Med., Newcastle-on-Tyne.

SOCIETY OF APOTHECARIES.—The following gentlemen, having satisfied the Court of Examiners as to their knowledge of the Science and Practice of Medicine, Surgery, and Midwifery, received certificates entitling them to practise as Licentiates of the Society on June 16th:—

Barton, George Pigott, Lympstone, Exeter, Devon.
Benson, Alfred Hugh, Marchlands, Stoke Bishop, Bristol.
Best, Norrys Dewes, Lime House, Walsall.
Brewis, Andrew Seymour, Eskdale-terrace, Newcastle-on-Tyne.
Hill, Edward Brereton, Longfleet, Poole, Dorset.
Mallard, Frank Reginald, Rosendale-road, West Dulwich.
Saunders, Henry, High-street, Eton.
Shemmonds, John Onley, Cambridge-road, Kilburn.
Wheeldon, Frederick John, Stockport-road, Manchester.

We are informed that the Final Examinations at the Society of Apothecaries will no longer be held every week, as hitherto, but once a month—viz., on the third Monday, Wednesday, and Thursday. The Primary Examinations will be held only once a quarter, of which due notice will be given.

ON the 21st inst. the foundation stone of the new Victoria Hospital, at Bournemouth, was laid amid great rejoicings. The estimated cost of the building is £7000.

Digitized by Google

THE seventh annual meeting of the Zenana Medical College was held at Exeter Hall on the 16th inst., when a satisfactory report was presented by the secretary and adopted.

LONDON FEVER HOSPITAL.—A loyal and congratulatory address has been forwarded by the nurses of this hospital to Her Majesty the Queen and very graciously accepted.

PRESENTATIONS.—On the 13th inst. Mr. J. G. Symes was presented by the officers and staff of the Dorset County Asylum with a handsome embossed silver bowl on an ebony stand, on the occasion of his retirement after more than thirty-two years' service as medical superintendent of that institution.——Mr. Waldy has been presented with two cases of surgical instruments by the students of the Newcastle-on-Tyne Infirmary, on the occasion of his retirement from the position of house-physician to that institution.

QUEEN'S COLLEGE, CORK.—The following class prizes have been awarded in the Faculty of Medicine:—First Year: Practical Anatomy—1st, Daniel O'Driscoll; 2nd, W. J. Prendergast. Second Year: The following have been awarded, in addition to those already published: Anatomy and Physiology—Thomas Jones. Practical Anatomy—3rd, Thomas Jones. Practical Chemistry—2nd, Thomas Jones. The exhibition in Practical Midwifery has been awarded to William J. O'Meara.

ILLEGAL PRACTICE IN FRANCE PUNISHED.—A bone-setter at Aubervilliers, being applied to by a man with a nasal polypus for advice, covered him with blisters from head to foot, and, by dint of promises to cure him, and threats about *le grand Albert* and *le Dragon-Rouge*, extracted 500 francs from his credulous patient. His illegal practice, however, was not allowed to go unpunished, for a French court sentenced him to three months' imprisonment, and his wife, who had been assisting him, to fifteen days' imprisonment.

VOLUNTEER AMBULANCE CORPS.—On the 18th inst., the non-commissioned officers and men trained as an ambulance for the 1st Volunteer Battalion, South Wales Borderers, were presented with the Geneva Cross and certificates of proficiency, as a bearer company, by Mrs. Somerset, wife of the Rev. B. Somerset, chaplain. The examining officer, Surgeon-Major Barrow, Army Medical Department, expressed himself in complimentary terms as to the high state of efficiency to which the men had been brought by Acting Surgeon Hill, who is in charge of the ambulance.

NORTH-EASTERN HOSPITAL FOR CHILDREN.—The annual meeting of the subscribers and friends of this institution, which is situated in the Hackney-road, was held on the 17th inst. From the report which was presented by the secretary, and subsequently adopted by those present, it appears that although the hospital had been closed for a month during the past year to in-patients, the number treated, 618, was larger than in any preceding year. There had been 14,083 new cases in the out-patients' department, with 50,170 new attendances, as compared with 13,801 patients and 46,164 attendances in the previous year.

METROPOLITAN FREE HOSPITAL.—On the 14th inst., at a special general meeting of the governors of this charity, it was decided that the word "Free" be omitted in the title, and that the institution be in future known as the Metropolitan Hospital. The following resolution was also adopted:—"That henceforth the institution be conducted on provident principles, no letter of recommendation to be required for any patient, and all cases of accident and urgency to be seen at once. The provident principle is that every patient shall contribute in health and sickness to the cost whilst under treatment, and that it be referred to the General Purposes Committee of Management to make provision and rules for carrying this principle into practice."

UNIVERSITY COLLEGE, LONDON.—A statement has been drawn up and signed by Lord Kimberley, late president, Lord Justice Fry, late vice-president, Sir Julian Goldsmid, late treasurer, and four members of the Council, for the purpose of laying before the members of the College the reasons which caused them to resign their seats on the Council. This step they have been compelled to take because they cannot concur with the resolutions passed by the Council on March 5th and May 21st in the present year with regard to the promotion of a Teaching University for London. They object to the proposal that the professors and teachers should confer degrees upon their own students; they object also to making attendance on a regular course of instruction in the College a condition of obtaining a degree; and, thirdly, they are convinced that the only prudent course for the College to adopt in the present crisis is to endeavour to maintain cordial relations with the University of London, and to seek for a more intimate union with it.

MEDICAL NOTES IN PARLIAMENT.

Smoke Nuisance Abatement (Metropolis) Bill.

IN the House of Lords on the 20th inst., on the order of the day for going into committee on this Bill, Lord Stratheden and Campbell complained of the sudden opposition which had sprung up on the part of Her Majesty's Government to this measure. He trusted that the Bill would be allowed to pass into committee or be referred to a select committee.—Earl Brownlow moved that the House do resolve itself into a committee on the Bill that day three months.—Earl Granville having expressed his disappointment at the want of action on the part of the Government, the Earl of Harrowby said that the time had come when some steps should be taken, as the present state of things was a scandal to our civilisation.—The Duke of Westminster hoped that the Government would consent to refer the Bill to a select committee. After some further discussion, in which Lord Mount Temple and Viscount Cranbrook took part, this suggestion was adopted, and the Bill was accordingly referred.

Vaccine Matter.

In the House of Commons, on the 16th inst., Mr. Burt asked whether the vaccine now in use was obtained by the inoculation of the cow with matter from the human subject in small-pox; whether such variolous vaccination was declared to be contrary to law by the Irish Local Government Board in 1879; and whether the Local Government Board agreed with that declaration.—Mr. Ritchie said the vaccine now in use was obtained by the inoculation of the cow with matter from a human subject.

Coal Mines Regulation Bill.

On the 20th inst. Mr. Matthews moved that the House go into Committee on this Bill.—Mr. Burt said that the Bill was a step in the right direction.—Mr. Staveley Hill asked the House to be very careful before they took away from the pit-brow women the power of earning their livelihood. Several members having spoken in support and criticism of the Bill, the debate was ultimately adjourned.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BAIGENT, WILLIAM, M.B., B.S., late Assistant Medical Officer to Dunston Lodge Asylum, has been appointed House-Surgeon to the Newcastle-on-Tyne Infirmary.

DAUNT, GEORGE, L.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the Third District of the Yeovil Union.

DAVIES, HUGH HUGHES, L.K.Q.C.P.I., has been appointed Medical Officer for the Western District of the Corwen Union.

HADDOW, R. W. TAYLOR, M.B., C.M.Glas., has been appointed Resident Medical Officer to the Stamford Hill, Stoke Newington, &c. Dispensary, vice C. A. James, M.R.C.S., L.R.C.P.Lond., resigned.

HARLOCK, HARRY, M.R.C.S., L.R.C.P.Lond., has been appointed Medical Officer for the Singleton District of the Westhampnett Union.

HEBBERTSWAITE, HAROLD, M.R.C.S., L.S.A., has been appointed Medical Officer of Health for Burley-in-Wharfedale, Yorks.

HUTCHINSON, JOHN H., M.R.C.S., L.S.A., has been appointed Medical Officer for the Catterick District of the Richmond Union (Yorks).

LOW, JOHN H., M.B., C.M.Glas., has been appointed Medical Officer for the Appleby District of the East Ward Union.

MAY, BENNETT, F.R.C.S., has been elected joint Professor of Surgery in the Queen's College, Birmingham, vice Furneaux Jordan, resigned.

PALIN, HENRY V., M.B., C.M.Ed., has been appointed Medical Officer for the First District of the Wrexham Union.

SHETTLE, HARRY WYNTER, L.R.C.P.Ed., M.R.C.S., has been appointed Assistant Surgeon to the Royal South Hants Infirmary, Southampton, vice A. B. Wade, M.B., C.M., M.R.C.S., appointed Surgeon.

TARGETT, JAMES HENRY, M.B., B.S.Lond., F.R.C.S.Eng., late Surgical Registrar to Guy's Hospital, has been appointed Sub-Curator of the Museum and Assistant Demonstrator of Pathology at Guy's Hospital.

WADE, ARTHUR BICKDON, M.B., C.M., M.R.C.S., has been appointed Surgeon to the Royal South Hants Infirmary, Southampton, vice George King, M.B., M.R.C.S., deceased.

WHITELEY, DANIEL FLOCKTON, M.R.C.S., L.R.C.P.Lond., has been appointed House-Surgeon to the Rochdale Infirmary, vice A. Watson, resigned.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

COVENTRY AND WARWICKSHIRE HOSPITAL. — House-Surgeon. Salary £100 per annum, with board (exclusive of beer, wine, and spirits), lodging, and attendance.

EAST SUFFOLK AND IPSWICH HOSPITAL.—House-Surgeon. Salary £100 per annum, with board, lodging, and washing.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.—Assistant Physician.

KENT COUNTY LUNATIC ASYLUM, Chartham Downs, near Canterbury.—Second Assistant Medical Officer. Salary £120 per annum, with furnished apartments, board, and attendance.

LIVERPOOL DISPENSARIES.—Assistant Surgeon. Salary £80 per annum, with apartments, board, and attendance.

MASON COLLEGE, Birmingham.—Professor of Physiology.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Librarian.

UNIVERSITY COLLEGE HOSPITAL, London. — Assistant Physician.—Assistant Surgeon.—Assistant Obstetric Physician.

WANDSWORTH AND CLAPHAM UNION.— Dispenser. Salary £80 per annum, rising £5 annually to a maximum of £100 per annum, with dinner and tea daily.

WEST-RIDING LUNATIC ASYLUM, Wakefield.—Resident Clinical Assistant. No salary, but board, apartments, &c.

Births, Marriages, and Deaths.

BIRTHS.

BRODIE.—On the 16th inst., at Downing-street, Farnham, Surrey, the wife of Wm. Haig Brodie, M.B.Ed., of a son.

BROWNRIGG.—On the 17th inst., at Hill House, Gravesend, the wife of J. Annesley Brownrigg, M.A., M.D., of a daughter.

CRIPPS.—On the 20th inst., at Stratford-place, W., the wife of Harrison Cripps, F.R.C.S., of a son.

DOUGHTY.—On the 21st inst., the wife of W. Doughty, M.R.C.S., Friern Lodge, Lordship-lane, Dulwich, of a daughter.

JULER.—At 77, Wimpole-street, W., the wife of Henry Juler, F.R.C.S., of a son.

SHORE.—On the 21st inst., at Crouch-hill, N., the wife T. W. Shore, M.D., B.Sc., of a son.

THURLAND.—On the 12th inst., at 184, Aldersgate-street, E.C., the wife of the late Francis Edward Thurland, M.R.C.S., L.S.A., of a daughter.

TREWMAN.—On the 18th inst., at Portsdown Lodge, Hants, the wife of Surgeon G. T. Trewman, Medical Staff, of a daughter.

WATERSCHOODT.—On the 16th inst., at Lewisham High-road, S.E., the wife of C. van Waterschoodt, M.D., of a daughter.

MARRIAGES.

CLOSE—SEAGAR.—On the 18th inst., at St. James's Church, Norlands, W., Henry A. Close, Fleet Surgeon, H.M.S. *Durham*, to Mary, daughter of the late Mark Seager, of Palermo.

DREW—BRADY.—On the 14th inst., at H.B.M. Legation, at Berne, and subsequently at the R.C. Chapel, W. B. Drew, Staff-Surgeon, R.N., to Edith, daughter of Henry Brady, of Thurleston Lodge, Ipswich.

GELSTON—RUDGARD.—On the 14th inst., at St. Thomas's Church, Heaton Chapel, near Manchester, John Seymour Gelston, L.R.C.S.I., L.K.Q.C.P.I., to Edith, second daughter of the late Francis Rudgard, of Bunker's-hill, Lincoln.

JAMES—PHILIPSON.—On the 21st inst., at Christ Church, Plymouth, by the Rev. B. Mills, M.A., assisted by the Rev. W. E. Roome, B.A., Charles Alfred James, M.R.C.S., L.R.C.P.Lond., D.P.H.R.C.P. & S., second son of John James, of Boon's-place, to Annie Lucy, eldest daughter of the late Rev. W. Philipson, M.A., Rector of Bradley, Lincolnshire, and granddaughter of the late Edward George Baron, M.R.C.S. (At home on Tuesday after July 25th, 24, Cazenove-road, Stoke Newington.)

MACDONALD—SYMES.—On the 15th inst., at Bradford Peverell, by the Rev. R. G. Watson, Rector of Gussage, All Saints, assisted by the Rev. E. J. Pope, Rector of Bradford Peverell, Peter William MacDonald, M.D., Medical Superintendent of the Dorset County Asylums, to Lydia Josephine Squire, eldest daughter of Joseph Gustavus Symes, late Medical Superintendent of the Dorset County Asylums, and granddaughter of the late Rear Admiral Symes, of Crewkerne.

MARSHALL—CHAMBERLAIN.—On the 18th inst., at St. Stephen's, Manchester, John G. Marshall, B.A., M.B., Clare Coll. Cambridge, M.R.C.S., to Lilian, only daughter of the late W. Mawer Chamberlain, of Barnsley.

DEATHS.

LINDSAY.—On the 16th inst. (of pneumonia), at Clifton-road, Maida-vale, W. William Vickress Lindsay, M.D., in his 40th year.

RENTZSCH.—On the 17th inst., at Chelsea, George Henry Rentzsch, M.R.C.S., L.S.A., formerly Army Medical Staff and District Medical Officer of Chelsea, aged 55.

TOPHAM.—On the 16th inst., at Collingham-road, South Kensington, John Topham, M.D., F.R.C.P., aged 66.

WILLMOTT.—On the 15th inst., at Weston-super-Mare, Alfred Willmott, M.D., aged 70.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

METEOROLOGICAL READINGS.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

A CURIOUS ADVERTISEMENT.

THE following is a curious advertisement:—"To Surgeons.—Wanted, a middle-aged single man or widower, who must be of good address, to attend for consultation daily at a patent medicine vendor's, to devote his whole time to the practice.—Address, in strict confidence, stating salary required, and with all particulars, to ——." What can be the need of a surgeon in the patent medicine department, where consultation is superseded and the medicines fitted by the patent to all cases and comers? It looks, too, as if the qualification of singleness or widowership were of more importance than the "ordinary qualifications." We cannot commend the appointment to any of our readers.

Ignoramus.—The 30th of June is the day after which such applications should be made. Our correspondent will ascertain the fee on inquiry of the registrar, 299, Oxford-street.

Quirens.—Most treatises on obstetrics supply the information.

TOWN SANITATION.

To the Editors of THE LANCET.

SIRS,—Some years ago in the town in which I reside the public slaughterhouse was removed to another part of the borough. The old building was then converted into four tenements, which have been since continuously occupied by poor families. Neither of these tenements has a back outlet, the privies are in small courtyards close to the entrance doors, and there is no proper drainage from them. A short time ago the sanitary committee of the Town Council requested the medical officer of health to inspect and report upon them. He pronounces them to be in a "perfect sanitary condition." As the committee hold a contrary opinion, and are anxious to have the cottages (?) removed, can you suggest how this is to be done in the face of the medical officer's report? I am, Sirs, yours truly.

June, 1887. A TOWN COUNCILLOR.

*** Proceedings can be taken by the sanitary authority under Section 9 of the Public Health Act, which deals with houses unfit for habitation, but it may be a question whether the court would be satisfied to act without medical evidence. Such evidence is, however, not necessary under the section. The proper remedy in such a case is to be in possession of an efficient code of bye-laws as to new buildings. Such bye-laws would come into operation, under Section 159 of the Public Health Act, on "the conversion into a dwelling-house of any building not originally constructed for human habitation." The Annotated Model Code of Bye-laws of the Local Government Board shows what should be required under such circumstances.—ED. L.

UNQUALIFIED ASSISTANTS AND THE JUBILEE.

Spes.—Our correspondent thinks the Jubilee ought to bring advantage to unqualified assistants, as well as to other unfortunate people, and he suggests how it might be so used. He proposes that within a given time each unqualified assistant be registered, and that on certain conditions of character and service he should be admitted to a *vivâ voce* examination and qualification to practise as an assistant surgeon only, and that at any subsequent time he should be allowed to present himself for examination at the conjoint examination of the Royal Colleges or other similar bodies *sine curriculo*. The idea is that ten years' service as an unqualified assistant is or should be considered equivalent to a curriculum. We believe that neither the Medical Council nor the medical bodies would agree to such proposals, which would neither be fair to the practitioners and students who go through the expensive and laborious system of medical education, nor to the public, which believes that in a recognised medical man they have one who has gone through this process. In the case even of the legal profession, though ten years' service as a managing clerk to a solicitor reduces the term of articles from five years to three, the three years' man has nevertheless to pass his intermediate and final examinations.

Mr. J. E. Edwards.—We are of opinion that the coroner was quite right not to pay our correspondent the fee. In fact, we believe he would have rendered himself liable to refund the guinea on its being disallowed by the magistrates. Our correspondent must look for payment to the person employing him.

J. Q.—The subject is discussed in our issue of April 16th.

THE HUTTON FUND.

To the Editors of THE LANCET.

SIRS,—May I again appeal to your kindness, and ask you to insert the enclosed list of subscriptions? The list will be kept open until Friday, July 15th, up to which date Dr. Cumberbatch, 25, Cadogan-place, Belgrave-square, will be glad to receive and acknowledge contributions.

I am, Sirs, your obedient servant,

W. HOWSHIP DICKINSON,
Secretary to the Committee.

June 20th, 1887.

THE NEW SANITARY CODE FOR ITALY.

THE sanitary interests of the Italian kingdom will henceforth be superintended by a Supreme Council of Health, to consist of a cabinet minister who will be president; the procurator-general of the Court of Appeal; a jurist; six doctors in medicine and surgery, specially qualified in public hygiene; a chemist; a pharmacist; a veterinary surgeon; three engineers, experts in sanitary architecture; a medico-sanitary inspector for the Army and a similarly qualified functionary for the Navy; the directors-general of the statistical bureaux and mercantile marine. Of these, six at least must be resident in Rome. In every provincial capital there will also be a council of Health, consisting of the prefect, the public prosecutor, a jurist, two doctors of medicine and surgery, a chemist, a pharmacist, a veterinary surgeon, and a sanitary engineer. For each district within the provinces there will be a similarly constituted Board of Health.

New Zealand.—Cassell's Domestic Medicine would probably answer the requirements of a person resident in a distant colony when beyond the reach of medical assistance.

Invalid should consult his medical attendant.

HEALTH OF THE "WILD WEST."

To the Editors of THE LANCET.

SIRS,—A rumour has been spread by some malicious person or persons that an outbreak of scarlet fever had occurred in the camp. We beg to state that, with the exception of accidents and one case of pneumonia (since recovered), there has been no case of illness, and the camp is and has been in a perfectly healthy state. It is open at all times to the inspection of the medical officer of health for the district.

Kindly insert this letter in your valuable journal, and oblige

Yours truly,

J. B. W. BIDLACK, M.D.Phil.U.S.A.,
Medical Director of the American Exhibition,
R. J. MAITLAND COFFIN, F.R.C.P.Ed.,
Medical Officer in charge of the Wild West Camp.

West Brompton, June 22nd, 1887.

NOVELISTS AND THE MEDICAL PROFESSION.

IN that clever and interesting novel by Maxwell Gray, "The Silence of Dean Maitland," which, though bearing this year's date, has already reached a fourth edition, there is a graceful allusion to the medical profession, the members of which receive but scant justice from novelists in general:—"The medical profession, strangely enough, has never been popular, skill in the healing art being usually attributed by the unlearned to the favour of the Evil One; a clever physician is prized and feared, but rarely loved. Even among the cultured there still lingers a faint repulsion for the man who is the only welcome guest in the day of sickness and peril, and society is only just beginning to honour the cultivated intellect and recognise the social value of the doctor." The real hero, and certainly the finest character in the book, Henry Everard, is a young surgeon, and when asking his clerical friend, Cyril Maitland, the future dean, for the reason why clergymen were more popular than doctors, received a reply in which the truth is somewhat satirically given: "Clergymen are of no use save at two or three august moments of life—when a man dies, gets married, or is born; therefore they inspire popular reverence as belonging to the ornamental and superfluous portion of existence, its fringes, so to speak. Doctors, on the contrary, cannot be dispensed with; their services are needed and obtained on the most homely occasions, and men never reverence the indispensable. Bread and cheese are taken as a matter of course, but the champagne of festivals is thought much of." The book will well repay the reading.

Mr. A. C. Cocks.—Our correspondent has a right to complain that he was not informed previously to his patient receiving a visit from the official medical adviser of the stores.

Mr. J. Harris Jones (Wilkes Barre).—We shall be pleased to receive the reports, and to give them our attention.

Dr. Birmingham (Dublin).—44, Fore-street, E.C.

REMOVAL OF BREAST TUMOUR WITH THE AID OF COCAINE.

To the Editors of THE LANCET.

SIRS,—Dr. H. F. Grün, in your issue of the 18th inst., publishes a case of removal of a tumour from the breast with the aid of cocaine, in which he confidentially asserts that "this is the first case in which a tumour of the breast has been removed under the influence of cocaine," but he neglects to give the date of his operation. I do not wish in the least to deprive him of any honour in being the first, but on May 29th, with the assistance of Dr. Stanley Ward, I removed with cocaine a much larger tumour, it being almost the size of a human kidney, together with a second growth nearly as large as a walnut. The incision was necessarily longer than in Dr. Grün's case. It was almost four inches in length. The parts were painted with a 20 per cent. and injected with a 10 per cent. solution in two places. It was not considered advisable to use chloroform from the condition of the heart. The patient felt a little pain, particularly when the final stitches were being inserted, probably from the effect of the cocaine passing off, but it must have been very slight, as she never moved even her arm during the operation. The wound healed by the first intention, the temperature did not rise above 100°, and within a week she was able to go out. I should not have thought of publishing this case, deeming it nothing exceptional, had not Dr. Grün made an assertion that his was the first case, which, of course, it still may have been, as he omitted to give any date.

I am, Sirs, yours faithfully,

Haverhill, June 21st, 1887. B. L. TANDY.

Alpha.—The coroner is bound to subpœna in statutory form. If our correspondent is not summoned, he must use his own discretion as to whether he will attend the inquest or not. It is certainly desirable that friction should be avoided between coroners and the medical representatives of large public institutions. In the case mentioned, our correspondent appears to have understood that his attendance would not be required, when in reality it was. A little give and take ought to have removed the misunderstanding. It is clear from the coroner's reply that he was cognisant of the fact that legally he was bound to command by subpœna the attendance and evidence of our correspondent.

Mr. A. J. Dalton.—In an early number.

Mr. Walter Greene.—The paper is marked for insertion.

ENCEPHALOCELE (?).

To the Editors of THE LANCET.

SIRS,—Four weeks ago I delivered a woman of a female child at full term. Labour was natural. After birth, the child was found to have a bilobed tumour behind and below the occipital bone. The tumour, I believe, contains the cerebra; it is the size of two oranges joined together, and is covered by a thin membrane, which gave way some days after birth and discharged a milky fluid. The discharge has since ceased. The usual prominence of the frontal region is absent. The cranial bones are more than usually ossified, no fontanelles being present. The child is strong and healthy, and takes the breast well. May I inquire how long such a child is likely to live, and what is the usual cause of death? I am, Sirs, yours truly,

June 21st, 1887. A. B.

DOCTORS' INCOMES.

Mr. D. Lloyd.—We regret to say that we think our correspondent's proposals unpractical. Nobody who studies the inability of Parliament to do its own proper work can fail to see the impossibility of its doing what our correspondent proposes. The profession must rely on itself, and certainly not on Parliament, to secure proper remuneration for its services.

Dr. Van Waterschoodt.—We do not know of an institution which would meet the requirements named.

Mr. Merces.—The letter is too long for insertion.

Dr. Beaven Rake is thanked.

ERRATA.—The remarks attached to the case of intubation of the larynx, published on page 1232 in our last number, were by mistake attributed to Drs. Smith and Waldo; they should have been credited to Mr. James Swayne.—The name of the recipient of a presentation, of which a notice was given on page 1164, should have been printed W. Jenner Clarke, not Reid.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Wm. Budd, Exeter; Dr. Dickinson, London; Mr. E. Owen, London; Prof. Roy, Cambridge; Mr. K. Millican, London; Mr. H. Travers; Dr. P. Blaikie Smith, Aberdeen; Rev. T. Dixon-Spain, Brlesdene; Dr. A. Thompson, Ulverstone; Mr. J. P. Gray, Halifax; Dr. Brett, Watford; Mr. B. L. Tandy, Haverhill; Mr. Bennett May, London; Mr. A. Wood; Mr. R. Jones; Dr. Lewers, London; Mr. T. J. Barnardo, London; Mr. T. Laffan, Cashel; Dr. Dunlop, Jersey; Mr. Benham, London; Dr. Percy Kidd, London; Mr. J. H. Jones, Wilkes Barre; Dr. Andrew Smart, Edinburgh; Dr. A. H. Hassall, Lucerne; Mr. Littlewood, Leeds; Dr. Fearnside, London; Mr. P. E. Hill, Crickhowell; Mr. Lennox Browne, London; Mr. R. B. Cooke, Scarborough; Messrs. Freeth and Co., Vauxhall; Mr. N. E. Davies, Sherborne; Messrs. G. Mason and Co., London; Mr. D. G. Marshall, Edinburgh; Surgeon-Major Briggs, Madras; Mr. Lyson, Burmah; Mr. Logan, Glasgow; Messrs. Isaacs and Co.; Mr. A. J. Dalton, London; Mr. Moore, Aden; Mr. Barlow, Birmingham; Mr. Jas. Swain, Bristol; Mr. Pease; Dr. McMurray, Liverpool; Mr. Henriques, London; Mr. J. Merces, London; Mr. G. Barling, Birmingham; Mr. Raw, Newcastle-on-Tyne; Messrs. Savory and Moore, London; Mr. Armstrong, Harpurhey; Mr. Skrimshire, Blaenon; Mr. Graham, Bristol; Mr. Fox, Manchester; Mr. Hawkins, London; Dr. Baker, York; Mr. Linsey, Mansfield; Mr. Symes, Dorchester; Mr. Ladd, Canterbury; D. Pressland, London; A Locum; H. D. F.; Coventry; Alpha, Clapham; M.D., Manchester; M.D., Suffolk; Francis; Ignoramus.

LETTERS, *each with enclosure*, are also acknowledged from—Dr. Squire, London; Dr. Juler, London; Lady Lambton; Messrs. Thomae and Co., London; Mr. Crewes, Truro; Mr. Lowther, Hull; Messrs. Morgan and Co., Morriston; Dr. Thompson, Oldham; Messrs. Hankin and Son, St. Ives; Mr. Simpson, Oydh; Mr. Evans, Oswestry; Mr. Rees, Brecknock; Mr. Fiske, Dawlish; Dr. Shore, Hornsey; Messrs. Blake and Co., Leeds; Mr. Lewis, Wakefield; Mr. Chadwick, Lancaster; Mr. Williams, Richmond; Mr. Bunbage, Coventry; Mr. Williams, Abertillery; Dr. Connon, Blackburn; Mr. Marsh, Wigan; Mr. Christie, Southsea; T. S., Lalon; P. K., Winchester; Alpha, Everton; Dragon; Medicus, Liverpool; Alpha; X.; Assistant, Hull; Surgeon, Liverpool; X. Y. Z., London; Surgeon, Bradford-on-Avon.

Orvosi Heti Szemle, Newcastle Daily Chronicle, Liverpool Evening Express, Scotsman, Scarborough Post, Glasgow Herald, &c., have been received.

MEDICAL SOCIETIES.

ACADEMY OF MEDICINE IN IRELAND.—Narcolepsy; Myxœdema, 25—Placenta prævia, 126—Parasitic disease of lungs of sheep; Stricture of œsophagus; Adenoma from mammary gland of rat; Simultaneous fracture of both clavicles; Cerebral meningitis and abscess, 177—Conservative surgery in diseases of foot and ankle; Addison's disease; Select clinical reports, 373—Ovarian tumour; Treatment of vaginismus; Porro's operation for rupture of the uterus, 527—Aspergillus nigricans; Dermoid tumour; Œdema glottidis, 580—The marsupial heart; Absence of the internal iliac artery, 733—Resection of the pylorus; Œsophagotomy to remove a foreign body; Diphtheria; Notes on insanity; Dystocia caused by hydrocephalus and pelvic tumour, 881—Malignant disease of the stomach, &c.; Fibro-sarcoma of the orbit; Trephining for epilepsy; Nerve suture; Excision of knee joint; Prevention and treatment of disease; Typhoid fever, 1090—Hxhibition of specimens; Treatment of vesico-vaginal and vesico-uterine fistulæ, 1136—Malignant disease of tonsil; Excision of wrist joint; Ideal paralysis; Calculous pyelitis, followed by albuminoid disease, 1234—Distribution of phthisis and diseases of the respiratory organs in Ireland, 1284
ANATOMICAL SOCIETY.—Propositions of committee and election of officers, 1186
CAMBRIDGE MEDICAL SOCIETY.—Pseudo-hypertrophic paralysis; General sarcomatosis; Death after washing out dilated stomach, 74—Abortion; Cystic ovaries removed for dysmenorrhœa; Hæmatocele from a ruptured Graafian follicle, 126—Severe injury to thorax; Thrombi in pulmonary vessels; Macro-glossia; Diphtheria, 527—Treatment of quinsy; Stellwag's symptom; Intra-uterine amputation of forearm, 734—Intussusception of bowel; Cyst of cerebellum, enclosed in fourth ventricle; Cerebellar tumour, 829—Dislocation of lens; Puerperal fever; Sanitation of the lying-in chamber, 1285

Digitized by Google

CLINICAL SOCIETY OF LONDON.—Athetosis and aphasia in a child; Treatment of cysts of thyroid; Treatment of imperforate anus, 174—President's address; Nephro-lithotomy; Renal surgery, 269—Discussion on nephro-lithotomy, 370—Paralysis of left leg from subcortical disease; Rheumatic hyperpyrexia successfully treated by the cold bath; Epilepsy following an injury to the leg; Profuse hæmaturia in connexion with granular kidneys, 471—Pneumothorax with recovery in the apparently healthy; Intra-peritoneal excision of rectum; Scoliosis, 574—Contraction of the metatarso-phalangeal joint of the great toe; Acute and chronic internal suppuration without fever; Glandular swelling curable by arsenic, 678—Inherited congenital deformity of hands and feet; Psoriasis, pityriasis, and rheumatism; Symmetrical gangrene following varicella; Intussusception produced by a tumour, 729—Difficulties in establishing natural respiration after tracheotomy; Large omental lipoma successfully treated by abdominal section; Abdominal exploration for chronic intestinal obstruction, artificial anus, removal of growth involving splenic flexure of the colon, 879—Abdominal cysts following injury; Spasmodic torticollis due to cerebral lesion; Gouty knee joint with suppuration; Intracapsular fracture of neck of femur, 1034—Acute cardiac dilatation from alcoholism; Endemic hæmaturia; Lupus treated partly by scraping and partly by salicylic paste; Hammer toe, 1135

EPIDEMIOLOGICAL SOCIETY.—Typho-malarial fever, 73—Preventive inoculations, 220—Cholera in India before 1817; Statistics of the West Ham Small-pox Hospitals during the epidemic of 1884 and 1885, 474—Observations on filaria sanguinis hominis in South Formosa, 732—The presence of mould fungi in connexion with diphtheria, 933—Tubercular infective areas, 1035

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—Injury in twin pregnancy, 27—A review of thirteen years' private (obstetric) practice, ib., 316—Exhibition of specimens, 781—Difficulties in private obstetric practice, 1137

HARVEIAN SOCIETY.—Peripheral neuritis; Paraplegia in Pott's disease; Dyspnœa from pressure of enlarged bronchial glands; Chylous ascites, 22—Analogy between croup and asthma; Suppurative peritonitis; Cancer and its treatment, 175—Extirpation of the axillary gland, as necessary accompaniment of removal of the breast for cancer, 627—Hereditary syphilis; Habitual constipation in children, 828

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—Oöphorectomy; Removal of ingrowing eyelashes by electrolysis; cataract; Hemiplegia, 26—Suprapubic lithotomy; Toxic effects of sulphate of dubolsin, 75—Palsy in limited groups of muscles; Pernicious anæmia; Primary nerve suture, 272—Resection of bowel for intussusception; Raynaud's disease; Treatment of mastitis; Dangers of cocaine, 780—Empyema, 1035—Diphtheritic slough of vagina; Estimation of the amount of urine voided by its weight; Therapeutic memoranda; Adenoid vegetations in naso-pharynx; Aneurysm of thoracic aorta, 1186

MANCHESTER PATHOLOGICAL SOCIETY.—Exhibition of specimens, 25—Diseases of the hip joint in children, 475—Thirty-seven calculi removed by lateral lithotomy; Mammary tumours; Changes in spinal cord and peripheral nerves after amputation, 628—Exhibition of specimens, 883

MEDICAL OFFICERS OF HEALTH SOCIETY.—Contagious Diseases (Animals) Act, 1886; Sanitary registration of buildings, 23—Legislation for the purification of rivers, and its failure, 315—Small-pox hospital influence, 421—The protective influence of vaccination, 580—Coal gas as a cause of sore-throat, 828

MEDICAL SOCIETY OF LONDON.—Phosphatic diabetes; Wound of common femoral vein, 125—Hunterian chancre of lower lip; Plastic operations for ectropion and contraction of face; Early colotomy, 218—Partial enterocele: Parotitis after abdominal operation; Rupture of aneurysm into pericardium, 314—Removal of both superior maxillæ, 372—The treatment of syphilis by mercury; Excision of half of larynx; Tuberculosis of fauces; Dislocation of both hips; Excision of hip; Trephining for cerebral abscess, 473—Annual general meeting; Perforation of femoral artery and vein from suppurating bubo, 526—"Clottage" of the ureters; Certain conditions of bladder in children, 576—Incision of swollen optic nerve sheath; Solvent treatment of renal calculus; Intussusception; Congenital defect in diaphragm, 626—Hereditary tremors; Random symptoms from cerebral syphilis; Facial monoplegia; Post-hemiplegic chorea; Jacksonian epilepsy; Ulceration of palate; Sarcoma of tonsil, 680—Ulcerative endocarditis; Alleged dangers of starch-containing foods during the period of infancy, 731—Treatment of hæmorrhage from the tongue; Catheter and calculi removed by lithotrity; Renal sarcoma in infancy, is surgery justifiable? 827—Blood cyst of tongue; Severe injury of wrist joint, with division of nerves, vessels, and tendons, treated by conservative surgery; Excision of nævoid growth in neck, 881

MEDICO-PSYCHOLOGICAL ASSOCIATION.—The Lunacy Acts Amendment Bill, 1035

MIDLAND MEDICAL SOCIETY.—Strangulated hernia; Fœtal abnormality; The leg type of progressive muscular atrophy, 26—Fracture of spine; Meckel's diverticulum, 316—Gunshot wound of vertebra; Fractured first rib; Rupture of abdominal aorta, 374—Locomotor ataxia with joint disease; Tumour of bladder treated by suprapubic cystotomy; Periosteal sarcoma; Injury to shoulder, 629—Chronic phlegmasia dolens; Gastric ulcer; Syphilitic stenosis of trachea; Epithelioma of male breast, 830—Talipes calcaneus; Ruptured brachial plexus, 1092

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—Hysterectomy; pseudo-hypertrophic paralysis, 27—On disinfection, 76—Treatment of lupus; Removal of uterine appendages; Athetosis, 830—Miscellaneous cases, 1092

OBSTETRICAL SOCIETY.—Midwifery among the Burmese; Stricture of the female urethra, 176—Unilateral galactorrhœa, 373—Galactorrhœa, 579—Mechanism of the third stage of labour, ib., 779, 1185—Hæmorrhagic parametritis; Frequency of pathological conditions of the Fallopian tubes, 982—Cæsarean section; Tubo-ovarian cysts, 1185

OPHTHALMOLOGICAL SOCIETY.—Treatment of conical cornea; Exostoses of skull, with atrophy of optic nerves; Unusual clinical cases; Acute cerebral disease, with ocular symptoms, 271—Ophthalmoplegia externa; Pupillary movement in lateral deviation; Tubercular (?) disease of choroid; Closure of sclerotic wound by conjunctival sutures only; Lateral nystagmus; Conjugate palsy of ocular muscles and nystagmus, 576—Franklin's spectacles; Insertion of artificial globes into Tenon's capsule after excising the eye; Night-blindness; Complete self-enucleation of eyeball, 983—Unicular optic atrophy and temporal hemianopsia; Permeability of the suspensory ligament by organised substances; Choroido-retinitis; Cyclotomy in glaucoma, 1283

PATHOLOGICAL SOCIETY.—Ulceration and endocarditis of right side of heart; Syphiloma of heart; Rare aneurysm of undefended space with cerebral tumour of brain (? syphilitic); Alcoholic paralysis; Ulcers of stomach in infantile tuberculosis, 21—Multiple cavernous angiomata; Melanotic tumour of breast; (?) Recovery from tubercular meningitis; Raynaud's disease and peripheral neuritis, 72—Hypertrophy of bladder; Lipoma of heart; Spontaneous disintegration of vesical calculi; Infantile palsy, 173—Genito-urinary disease in animals; Pathology of Colles' fracture; Extra-uterine fœtation; Rupture of bladder; Cerebral tumour; Multiple perforative necrosis of skull of tubercular origin, 268—Shedding of teeth in tabes dorsalis; Intermuscular synovial cysts; Endothelioma of dura mater; Syphilitic hyperplastic laryngitis; Mitral aneurysm in a child; Ectopia vesicæ; Retro-pharyngeal abscess; Horny growth on penis, 420—Adeno-sarcoma of tongue, with calcifying nodule in centre; Alveolar sarcoma; Malarial diseases of liver and spleen; Extra-uterine pregnancy; (?) Cirsoid aneurysm; Cholesteatoma at base of brain, 524—Fibroma of ovarian ligament; Metastatic carcinoma of prostate; Large dermoid cyst over sternum; Gall-stone causing obstruction of bowel; Cystic disease of testicle; Cystic epithelioma of neck, 573—Alveolar ulceration in a child with general tuberculosis; Hypertrophic goitre, with secondary tumours in bones of skull; Tumour of pineal gland; Chronic inflammatory disease of uterine appendages; Meningeal cerebral hæmorrhage, with secondary degeneration of spinal cord, 777—Congenital dislocation of hip; Disease of humerus (? osteitis deformans, or osteomalacia); Fibrous metaplasia of bone, 825—Destructive arthritis of knee without suppuration; Senile arthritis; (?) Sarcoma of knee; Carcinoma of spine and liver; Diffuse sarcoma of spinal pia mater; Interstitial aneurysm of inter-auricular septum; Tubal pregnancy, 931—Multiple neuro-fibromata and molluscum fibrosum; Sarcoma of pelvic fascia; Cerebral hæmorrhage in a child with thrombosis of sinuses; Rickets in the skulls of lions; Suprapubic abscess; Cultivation experiments with new growths, 1032

PLYMOUTH AND DEVONPORT MEDICAL SOCIETY.—Treatment of typhoid fever, 375

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—Suture of divided nerves; Physiological effects of massage, 124—Surgical treatment of hydatids of the liver, 217—"Induration" of Hunterian chancres in the female; Actinomycosis hominis, 313—Rupture of urinary bladder, 418—Annual general meeting; President's address, 471—Gouty parotitis and Gouty orchitis; Empyema, with pulmonary gangrene, following enteric fever, treated by perfiation, 523—Obstruction of one ureter by a calculus, associated with complete suppression of urine; Sacculated kidney containing calculi, with disorganisation of the other kidney, and associated with complete suppression, 625—Abdominal and thoracic aneurysms treated by the introduction of steel wire into the sac, 775—Chronic syphilitic meningitis, causing progressive dementia; Analysis of 93 cases of writers' cramp, and impaired writing power, 878—Rectal intussusception, due to a new growth; Experimental inquiry as to the best method of enterorraphy, 980—Relation of a certain form of headache to the excretion of uric acid; Alcoholic paralysis, 1088—Dermatitis gangrenosa infantum; A form of inflammation of the lips and mouth usually attended by some disease of the skin, 1233

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—Large thrombus of the right labium; Poisoning by cocaine; Biliary calculi; Locomotor ataxy; Cause of death in malignant fever, 75—Malignant disease of pancreas and liver; Graves' disease, 273—Thoracic aneurysm; Aortic disease; Supra pubic suppuration; Plumbism, 681—Injury of popliteal artery; Hodgkin's disease; Tumour in right iliac region; Intestinal obstruction; Double ophthalmoplegia; Acute dilatation of stomach, 882—Malignant tumour of the œsophagus; Pemphigus neonatorum; Sarcomatous tumour of the uterus, 1236

WEST KENT MEDICO-CHIRURGICAL SOCIETY.—Diagnosis of traumatic separation of the epiphyses, 934

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—Etiology of phthisis; Surgical treatment of tuberculosis, 219—Urethral calculus, 681—Some of the rarer forms of rectal fistulæ; Selection and administration of anæsthetics, 1089

WIGAN MEDICAL SOCIETY.—Attendance of medical witnesses at assize courts, 273

WOLVERHAMPTON AND DISTRICT MEDICAL SOCIETY.—Use of axis-traction forceps in midwifery, 127—Adenoid bronchocele; Diagnosis of intestinal obstruction, 374

YORKSHIRE ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—Outbreak of diarrhœa caused by the emanation of noxious gases from tide-locked sewers, 76

Medical Society of London, annual general meeting at the, 526, 945
——— students' statistics, relating to, during the quinquennium 1871-75, 92
——— titles, fine for false use of, 540
——— trials, 601, 1259

MIRROR OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

BIRMINGHAM GENERAL HOSPITAL.—Cases of ovariotomy, 1283
BRISTOL ROYAL INFIRMARY.—Three cases of intubation of the larynx, 1232
BURTON-ON-TRENT INFIRMARY. — Crushed pelvis; rupture of bladder; necropsy, 172
CHARING-CROSS HOSPITAL.—Strangulated congenital hernia with rupture of intestine; herniotomy; entorraphy; cure, 521—Fracture through sarcoma of femur; secondary deposits in skull and clavicle; death; necropsy, 624—Sarcoma of lung following amputation of right thigh sixteen months previously, 727
CROYDON INFIRMARY.—Acute internal strangulation, 1031
DEACONESSES' INSTITUTION AND HOSPITAL, TOTTENHAM.—Cerebral embolism following parturition; hæmorrhage into lateral ventricle; death; necropsy, 19
DEVON AND EXETER HOSPITAL.—Unilocular ovarian cyst in a girl aged thirteen; ovariotomy, 418
DORSET COUNTY HOSPITAL.—Suprapubic lithotomy, 1031
DUNDEE ROYAL INFIRMARY.—Acute sporadic cerebro-spinal meningitis; death on fourth day; necropsy, 312
EDINBURGH ROYAL INFIRMARY. — Traumatic tetanus cured by removal of the cicatrix and surrounding parts, 21
GENERAL LYING-IN HOSPITAL.—Cervical emphysema following parturition, 122
GUY'S HOSPITAL.—Seven consecutive cases of charbon treated successfully by excision, 367, 416—Sarcoma of the femur; death following necrosis of the lower jaw, 773—Colotomy for malignant disease, 823—Fracture of tibia due to necrosis, ib.—Removal of foreign body from antrum, 823—Popliteal aneurysm treated by digital compression; cure after previous failure with Esmarch's bandage and electrolysis, 1230—Round-celled sarcoma after prolonged suppuration of antrum; partial excision of superior maxilla, ib.
HAMPSTEAD HOME HOSPITAL.—Chronic renal abscess; abdominal renal nephrectomy; recovery, 1282
HERTFORD GENERAL INFIRMARY.—Removal of the coccyx, 1068—Hypertrophy of spleen; death; necropsy, 1184
HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.—Disease of knee joint; diphtheria followed by extensive paralysis; recovery, 677—Suprapubic lithotomy; hæmorrhage into the bladder; recovery, 939
LEEDS GENERAL INFIRMARY.—Compound fracture of skull; trephining; spasm of muscles of face and arm; second trephining over fissure of Rolando; recovery, 774
LEICESTER INFIRMARY.—Suprapubic lithotomy in the adult; suture of bladder; primary union, 267—Abdominal section for internal strangulation; formation of artificial anus; enterectomy; cure, 728
LONDON HOSPITAL. — General tuberculosis; necropsy, 18—Hepatic abscess, 215—Foreign body in the urethra; removal, 470
MANCHESTER ROYAL INFIRMARY. — Hydatid cyst of liver; resection of rib; removal of cyst wall, 624—Active traumatic suppurative osteomyelitis of humerus; early employment of the trephine; recovery, 824—Rupture of spongy urethra; suture; recovery, 877—Perineal and suprapubic cystotomy combined, 980
MIDDLESEX HOSPITAL.—Pylorectomy for carcinoma; death; necropsy, 171—Sarcoma of scapula, thigh, and femur, 1036—Sarcoma of knee, foot, and ear, 1183
NEWCASTLE-ON-TYNE INFIRMARY.—Two cases of suprapubic lithotomy, 123—Hernia of ovary, 312—Diffused traumatic aneurysm of anterior tibial artery; attempted ligature; amputation, 522—Epithelioma of soft palate, ib.—Jaw cases, 930
NORTH-EASTERN HOSPITAL FOR CHILDREN.—Two cases illustrating the treatment of the deformity following tubercular disease of the knee joint, 216—A case of acute meningitis in which complete recovery took place, 368
NORTH-WEST LONDON HOSPITAL.—Stricture of urethra presenting unusual difficulties, 979
NORWOOD COTTAGE HOSPITAL.—Multilocular ovarian tumour, with umbilical hernia, complicated with pelvic adhesion; recovery, 1087
ROYAL HOSPITAL FOR DISEASES OF THE CHEST, CITY-ROAD.—Empyema; free incision and drainage at lowest point; rapid recovery, 571
ST. BARTHOLOMEW'S HOSPITAL.—Sarcoma of tongue; removal of half of tongue; recovery, 623
ST. GEORGE'S HOSPITAL.—Compound depressed fracture of vault of skull; paralysis of right arm; trephining; recovery, 122—Cerebro-spinal meningitis; recovery, 571—Complicated case of intussusception in a child; operation; death; necropsy, 1030
ST. MARY'S HOSPITAL.—Partial enterocele; gangrene; recovery, 311—Gall-stones in the cystic duct; cholecystotomy; recovery, 1282
ST. THOMAS'S HOSPITAB.—Case of inguinal and two of umbilical hernia, in which radical cure was performed, 69—Suprapubic lithotomy in a man aged seventy-two; cure; death from apoplexy, 265—Bullet wound of chest; wound of lung; removal of bullet; recovery, 266—Successful removal of right ovary for cystic disease nine months after operation for hydrosalpinx, 876—Extravasation of blood into the thigh; general tuberculosis; necropsy, 877
ST. VINCENT'S HOSPITAL, DUBLIN.—Two cases of abscess evacuated without any resulting disfigurement, 217—Perforating ulcer of the stomach, 267—A fatal case of paraplegia; necropsy, 470
SAMARITAN HOSPITAL FOR WOMEN, NOTTINGHAM.—Cases of abdominal section, 1134
SEAMEN'S HOSPITAL, GREENWICH.—Surgical cases of interest, 572
SOUTH DEVON AND EAST CORNWALL HOSPITAL, PLYMOUTH.—Removal of upper extremity, and later of scapula and part of clavicle, for sarcoma, 20
STAMFORD INFIRMARY.—Calculus in a boy; removal by lateral lithotomy; cure, 71—Calculus vesicæ; suprapubic operation; death; necropsy, 1185
SWANSEA HOSPITAL. — High aneurysm of femoral artery; ligature of external iliac artery; cure, 71
UNIVERSITY COLLEGE HOSPITAL.—Three cases of badly united fracture of the femur, 469
VICTORIA HOSPITAL FOR CHILDREN.—Operation for cleft palate in children of twelve months of age, 1133—Traumatic stricture in a child aged three years, 1231
WEST LONDON HOSPITAL.—Partial paraplegia, probably due to syphilitic meningitis; recovery, 172
WESTMINSTER HOSPITAL.—Case of Addison's disease; necropsy, 676—Punctured wound of brachial artery; arrest of hæmorrhage by pressure; secondary bleeding; ligature of vessel, 978
WOLVERHAMPTON GENERAL HOSPITAL. — Multiple aneurysms of the arch of the aorta, 1032
WOLVERHAMPTON AND SOUTH STAFFORDSHIRE GENERAL HOSPITAL.—Rupture of popliteal artery and vein; amputation, 523

Mitchell, Dr. S. W., Wear and Tear (review), 783
——, Mr. H., on primary Hunterian chancre of the cheek, 622
Mitra, Mr. A., on a case of lacerated wound treated with iodoform, 468
Mitral aneurysm in a child, 421

"Tear" of public life, the, 1103
Teeth, the density of the, as influenced by the food, 46; the effect of a diet without lime upon the, 78; replantation, transplantation, and implantation of, 334
Telegraph, consultations by, 220; and telephone wires, overhead, 40
Temperance Hospital, the, 1164
Temperature, extremes of, 1248
Tendo Achillis, suture of, 16
Terrier's nephrectomy, 1145, 1262
Tertiary alcohols, 1256
Testes and cord, tumours of, 22
Testicle, cystic disease of the, 573
Tetanus, successfully treated with chloral hydrate, a case of, 264; traumatic, cured by removal of the cicatrix and surrounding parts, 21; traumatic, successfully treated by the subcutaneous injection of morphia, 170; traumatic, case of, 367
Thames, pollution of the, 1118; contamination of the, by the Henley regatta, 1294
——— Valley Drainage Board, another, 858
Theatres Bill, 899
Theatres, the ventilation of, 82; panics in, 689; the regulation of, 692; luminous paint in, 1001
Thermometer, unbreakable clinical, 318
Thigh, fracture of the, during parturition, 505; extravasation of blood into the, general tuberculosis, necropsy, 877
Thiriar, Dr., on varicocele, 893
Thomas, Mr. D. H., presentation to, 246
———, Mr. W. E., on chronic rheumatic arthritis, 1167
Thompson, Dr. W. S., on vaccination and revaccination, 605
———, Mr. C. R., obituary notice of, 1067
———, Sir Henry, the Diseases of the Prostate, their Pathology and Treatment (review), 28
———, Thomas, respite of the convict, 390
Thomsen's disease, cases of, 972, 1047
Thoracic aneurysm, 681
——— aorta, aneurysm of, 1186
Thorax, severe injury to, 527
Thornton, Mr. W. H., obituary notice of, 703
Threadworm, 1119, 1167
Thrombi, the formation of, in pulmonary vessels, 527
Thrush, polymorphism of the fungus of, 1099
Thurstan, Dr. E. P., on sea-sickness, 350; on a doctor's income, 849, 1062
Thyroid, treatment of cysts of, 174, 238; and cerebral circulation, relations between the, 891
Thyrotomy for epithelioma of the larynx, 1029
Tibia, fracture of the, due to necrosis, 822; and ankle joint, a case of tubercular disease of the, treated by scraping away the medulla of the former and the synovial membrane of the latter, 771
Tibial artery (anterior), diffused traumatic aneurysm of the, of ten weeks' duration, attempted ligature, amputation, 522
Tinned milk, decomposition in, 87; extensive seizure of decomposed, 602
Tomes, Dr. A., on abscess of the liver in India, 110
———, Mr. C. S., on the effect of a diet without lime upon the teeth, 78
Tongue, adeno-sarcoma of, calcifying nodule in centre, 524; removal of half of, for sarcoma, 623; treatment of hæmorrhage from the, 827; blood cyst of the, 881
Tonsil, sarcoma of, 681; incising the, 1214; malignant disease of the, 1234
Tonsillitis, bicarbonate of soda in, 41; and diphtheria, 896
Tooth, torsion of an incisor, 232; pyæmia after extraction of a, 236
——— brush, a new form of, 784
——— extraction, conditions of successful production of local anæsthesia in, 589
——— powders, 37
Topham, Dr. J., obituary notice of, 1312
Torquay, health of, 646
Torticollis, spasmodic, due to cerebral lesion, 1034
Total abstinence lodges and medical prescription, 139
Tottenham hospital, 1115
Toulon, sanitation at, 151
Town refuse in road-making, the use of, 444
——— sanitation, 1314
Towyn, health of, 797
Toxteth Park, health of, 797; poisoning case, the, 892

BAILLIERE, TINDALL, & COX'S BOOKS.

This day, price 5s.

Handbook of Medical Pathology.

Being Lectures delivered at the London Hospital during the session 1885.

By HY. G. SUTTON, M.B., F.R.C.P. Lond.,
Physician and Lecturer on Pathology at the London Hospital.

Eighth Edition, price 18s.

Modern Medical Therapeutics.

A Compendium of recent Formulæ and Specific Therapeutics.

By G. H. NAPHEYS, A.M., M.D.

"A summary of the best modes of treatment."—PRACTITIONER.

Seventh Edition, price 18s.

Modern Surgical Therapeutics:

English, American, and Foreign.

By G. H. NAPHEYS, A.M., M.D.

"The volume will supply what many practitioners are often anxious to possess for reference in the practice of their art."—GLASGOW MED. JOUR.

"Invaluable to every practising physician."—MEDICAL RECORD.

Lupus: A Pathological and

CLINICAL INVESTIGATION INTO ITS ORIGIN, DEVELOPMENT, and TREATMENT. Price 1s.

By ARTHUR HARRIES, M.D., and C. M. CAMPBELL, M.D.

Scabies: Its Causation, Diagnosis,

and TREATMENT. Price 6d.

A Lecture delivered at St. John's Hospital for Skin Diseases.
By ARTHUR HARRIES, M.D.

This day, Third Edition, price 7s. 6d.

Griffiths' Text-book of Materia

MEDICA AND PHARMACY.

Edited by A. S. GUBB, L.R.C.P., M.R.C.S.,
Gold Medallist, Prizeman in Materia Medica, Westminster Hospital.

*** The new Edition is brought up to latest date; is larger and cheaper than previous Editions. It contains also "GRIFFITHS' NOTES on the PHARMACOPŒIAL PREPARATIONS," and forms a complete text-book of Materia Medica and Pharmacy.

Bound leather, gilt edges, price 5s.

Practical Guide to the Public

HEALTH ACTS and CORRELATED ACTS, for the use of Medical Officers of Health and Inspectors of Nuisances.

By THOS. WHITESIDE HIME, B.A., M.B.,
Medical Officer of Health for the Borough of Bradford, lately Medical Officer of Health for the Borough of Sheffield.

Crown 8vo, price 5s.

The Laws relating to Medical Men.

By JAMES GREENWOOD, Barrister-at-Law.

"Admirably suited as a guide to the busy practitioner, who frequently runs great risks of becoming involved in legal penalties, in consequence of an imperfect knowledge of the law."—GLASGOW MEDICAL JOURNAL.

Demy 8vo, price 3s. 6d.

Vascular Deafness: A New System

OF AURAL THERAPEUTICS AND PATHOLOGY.

By ROBERT T. COOPER, M.A., M.D. Univ. Dub.

Now ready, price 3s. 6d., leatheretta.

The Pocket Pharmacopœia.

A Précis of the New British Pharmacopœia for Ready Reference, including the Therapeutical Action of the Drugs, their Natural Orders and Active Principles.

By C. ARMAND SEMPLE, M.D., M.R.C.P. Lond.

London: BAILLIERE, TINDALL, & COX, 20, King William Street, Strand.

Third Edition, in two vols., 2185 pp., 1090 Woodcuts, price 36s.

The Science and Practice of Surgery.

By FREDERICK J. GANT, F.R.C.S.,
Senior Surgeon to the Royal Free Hospital.

"Presents to the reader the modern aspects of surgery."—THE LANCET.

"The student or practitioner who consults this work may be sure of getting plenty of information on all subjects. The result is highly creditable for any single mind to have produced."—EDIN. MED. JOUR.

"Throughout it bears the impress of mature thought, and of critical judgment in the treatment of disease, from a mind stored with the teaching of a long experience."—INTERNAT. JOUR. MED. SCIENCES.

Fifth Edition, with numerous Illustrations, 12s. 6d.

Diseases of the Bladder, Prostate

GLAND, and URETHRA, including URINARY DISHASES, DEPOSITS, and CALCULI. By FREDERICK J. GANT, F.R.C.S.

"The work throughout bears evidence of having been written by a thoroughly practical and experienced surgeon."—THE LANCET.

"It is specially useful to the practitioner."—EDIN. MED. JOUR.

London: Baillière, Tindall, & Cox, 20, King William-street, Strand.

Now ready, Third Edition, Enlarged, and chiefly Rewritten, with Coloured Plates, price 12s. 6d.

DISEASES OF THE EAR.

By GEORGE P. FIELD, M.R.C.S.,
Aural Surgeon to St. Mary's Hospital, and Lecturer on Aural Surgery in the Medical School.

"Very practical and helpful."—THE LANCET.

"Forms an excellent guide for the practitioner or the student."—BRIT. MED. JOUR.

"It is a practical treatise founded on vast clinical experience. The illustrations are excellent and helpful, the text is clear and concise, and the work as a whole is as complete and trustworthy as we could desire. We recommend it strongly to practitioners and students alike."—MEDICAL PRESS AND CIRCULAR.

"It contains a novel feature: a number of plates are given on thick cardboard; the spot where the membrana tympani ought to be seen is perforated, and a coloured representation of the drum is pasted on behind. If the membrane be looked at through a speculum, a more correct idea than any heretofore given will be the result."—MED. TIMES AND GAZ.

"One of the most useful and practical guides to the treatment of diseases of the ear that have ever been published in this country."—THE LONDON MEDICAL RECORD.

"Most suitable as a text-book for the student, for the practitioner, or aural surgeon."—EDIN. MED. JOUR.

London: H. Renshaw, 356, Strand.

In crown 8vo, price 5s., with Illustrations.

Morbid Cardiac Conditions,

including the "Cartwright" Prize Essay on "The Heart in Debility." By WILLIAM RUSSELL, M.D., F.R.C.P. Edin., Lecturer on Pathology in the School of Medicine, Edinburgh.

"It cannot fail to be read with profit both the facts it brings to light and for the ideas it suggests."—THE LANCET.

"Certain to command the attention of everyone engaged in the investigations of cardiac diseases."—LIVERPOOL MEDICO-CHIRURGICAL JOURNAL.

"A contribution of real value and great interest."—MEDICAL PRESS.

Bell & Bradfute, Edinburgh. Simpkin & Co., London.

Now ready, Third Edition. Adapted to the New British Pharmacopœia, 1885. Medium 8vo, price 21s.

A Text-book of Pharmacology, Thera-

PEUTICS, and MATERIA MEDICA. By T. LAUDER BRUNTON, M.D., D.Sc., F.R.S., Fellow of the Royal College of Physicians; Assistant Physician and Lecturer on Materia Medica at St. Bartholomew's Hospital; Examiner in Materia Medica in the University of London, in the Victoria University, and in the Royal College of Physicians, London; late Examiner in the University of Edinburgh. Adapted to the United States Pharmacopœia by F. H. Williams, M.D., Boston, Mass.

"It is simply a mine of wealth both for students and practitioners. It is thoroughly practical and thoroughly reliable. ..... It is undoubtedly the best treatise on the subject in the English language."—BRITISH MEDICAL JOURNAL.

"A work which marks a distinct epoch, a turning-point in the history of medicine. It is not a mere compilation, ... but it is essentially a new departure, breaking away from well-worn tracks into a new and almost unknown region."—MEDICAL TIMES AND GAZETTE.

BY THE SAME AUTHOR.

Disorders of Digestion: Their Con-

SEQUENCES AND TREATMENT.—This Work contains, in addition to the Lettsomian Lectures, a number of other Papers by the Author on similar subjects. 8vo, 10s. 6d.

"Distinguished by accurate observation and original thinking, these papers have been largely instrumental in moulding current medical opinion in regard to many of the subjects with which they are concerned."—EDINBURGH MEDICAL JOURNAL.

"We can cordially recommend the volume, as one which combines much practical and technical information and sound common sense."—LONDON MEDICAL RECORD.

London: Macmillan & Co.

H. K. LEWIS'S RECENT PUBLICATIONS.

Just published, complete in One Volume, imperial 8vo, with 111 Illustrations, cloth, 28s.

A Text-book of Medicine for Students and Practitioners. By Dr. Adolf Strumpell, Director of the Medical Clinic in the University of Erlangen. Translated from the latest German Edition by Dr. H. F. VICKERY and Dr. P. C. KNAPP, with Editorial Notes by Dr. F. C. SHATTUCK, Visiting Physician to the Massachusetts General Hospital, &c.

"Of the German text-books of practice that have been translated into English, Professor Strümpell's will probably take the highest rank. Between its covers will be found a very complete and systematic description of all the diseases which are classed under the head of internal medicine ..... It is one of the most valuable works on practice that we have, and one which every studious practitioner should have upon his shelves."—NEW YORK MEDICAL JOURNAL, Jan. 29th, 1887.

Now ready, with Coloured Plates, crown 8vo. 8s. 6d.

On Fevers; their History, Etiology, Diagnosis, Prognosis, and Treatment. By ALEXANDER COLLIE, M.D. Aberd., M.R.C.P. Lond., Medical Superintendent of the Eastern Hospitals; Secretary of the Epidemiological Society for Germany and Russia. [*Lewis's Practical Series.*

"Like the other volumes of the same series, this work comes from thoroughly competent hands. Dr. Collie's reputation is itself sufficient guarantee for the excellence of any book on fevers that may bear his name. ..... Dr. Collie's work deserves and will receive a hearty welcome from the profession, and will take an established place amongst our special text-books, and because we should rejoice to see its usefulness increased and rendered more available."—PRACTITIONER, April, 1887.

"The work is an essentially practical one, and calculated to be of real service. Distinct without dogmatism, scholarly without pedantry, and the outcome of an almost unprecedented experience, it is worthy of the high literary and scientific reputation of the author, and will be warmly welcomed by his professional brethren as a standard text-book on the subject."—BIRMINGHAM MEDICAL REVIEW, April, 1887.

Now ready, crown 8vo, 8s. 6d.

Elements of Materia Medica and Pharmacy. By ALFRED W. GERRARD, F.R.C.S., Examiner to the Pharmaceutical Society, Teacher of Pharmacy and Demonstrator of Materia Medica to University College Hospital, &c.

Just published, Eighth Edition, demy 32mo, 1s. 6d.

Syllabus of Materia Medica: for the Use of Students, Teachers, and Practitioners. Based on the relative values of Articles and Preparations in the British Pharmacopœia (1885). By Drs. HARVEY and DAVIDSON.

Just published, Second Edition, Enlarged and Rewritten, 8vo, 466 pp., 14s.

General Paralysis of the Insane. By WILLIAM JULIUS MICKLE, M.D., M.R.C.P. Lond.

"The new edition of this exhaustive monograph is to a large extent a new book, contains nearly double the amount of matter presented in the first edition, introduces many new points, and also treats old subjects on entirely new lines."—THE LANCET.

"The only book in the English language which is at all up to our present knowledge of general paralysis."—BRITISH MED. JOURN.

"We have rarely welcomed a book more heartily than we have this by Dr. Mickle. ..... We recommend all our readers to get this book—a text-book for workers, and a repository of knowledge for all who seek it."—JOURN. MENTAL SCIENCE.

Nearly ready, Second Edition, post 8vo, 7s. 6d.

Indigestion and Biliousness. By J. Milner FOTHERGILL, M.D., M.R.C.P., Physician to the City of London Hospital for Diseases of the Chest, Victoria-park, &c.

Now ready, Seventh Edition, with 12 full-page Plates, 5 being Coloured, and 165 Wood Engravings, 1081 pages, royal 8vo, 35s.

Obstetrics; The Theory and Practice: including the Diseases of Pregnancy and Parturition, Obstetrical Operations, &c. By P. CAZEAUX, Adjunct Professor in the Faculty of Medicine of Paris, &c.; and S. TARNIER, Professor of Obstetrics and Diseases of Women and Children in the Faculty of Medicine of Paris. The Translation edited and revised by ROBERT J. HESS, M.D.

Third Edition, crown 8vo, 3s. 6d.

Gout and its Relations to Diseases of the LIVER and KIDNEYS. By ROBSON ROOSE, M.D., Fellow of the Royal College of Physicians in Edinburgh.

"It is one of the clearest and most complete reviews, in a small space, of existing knowledge with regard to this disease which we remember to have read, and it may be strongly recommended to the study of the young practitioner."—BRITISH MEDICAL JOURNAL.

"A record of personal observation and individual thought."—BRISTOL MED. CHIR. JOUR.

J. & A. CHURCHILL'S PAGE

The Principles and Practice of Medicine. By C. Hilton Fagge,

F.R.C.P. Edited by P. H. PYE-SMITH, M.D., F.R.C.P., Physician to, and Lecturer on Medicine at, Guy's Hospital. In
8vo, cloth, £1 16s.; also in half-persian, marbled edges, £2 2s.

"These two volumes represent the fruit of a busy, studious life, devoted to the study of scientific medicine. . . . . A perusal
shows that it is one of the most scientific and philosophical works of its kind, being in truth a mine of clinical and pathological facts
dealt with in so masterly a manner that we know not which to admire most—the patient labour and thought expended in bringing them
the learning and acumen that illustrate them, or the calm and judicial spirit in which they are estimated and criticised."—THE LANCET.

"To class it as the best work on its subject in the English tongue, the product of one brain, would but imperfectly express our estima
EDIN. MED. JOUR.

The Practice of Surgery: a Manual. By Thomas Bryant, F.R

Surgeon to Guy's Hospital. Fourth Edition (12th Thousand), thoroughly Revised and Enlarged, with 750 Illustrations,
Coloured, and including 6 Chromo-lithographic Plates specially drawn for this Edition. Two vols., crown 8vo, 32s.

"By its style and arrangement, by the comprehensiveness of its survey, and by the nature and quality of its subject-matter, both as to text and illustrations, the new edition may be confidently recommended as an excellent manual for the student, and as a safe, sure guide for the practitioner to every department of surgery."—THE LANCET.

"It teems with useful information. The fourth edition con
additions that greatly augment the value of the manual."
JOUR.

"There is not a practitioner or student in these countries
familiar with 'Bryant's Surgery' as one of the most useful
books in his library."—DUB. JOUR. OF MED. SCIENCE.

Physical and Inorganic Chemistry.

By HENRY WATTS, B.A., F.R.S., Author of "A Dictionary of Chemistry," &c. With Coloured Plate of Spectra and 150 Wood Engravings, crown 8vo, 9s.

Chemistry of Carbon Compounds; or, ORGANIC CHEMISTRY.

By HENRY WATTS, B.A., F.R.S. Second Edition, by WILLIAM A. TILDEN, D.Sc., F.R.S., Professor of Chemistry in the Mason College, Birmingham. With Engravings, crown 8vo, 10s.

*** These two volumes are based on the well-known Manual of the late Professor Fownes, and form the Thirteenth Edition of that work.

Introduction to General Pathology,

founded on Lectures delivered at the Royal College of Surgeons. By J. BLAND SUTTON, F.R.C.S., Assistant-Surgeon and Lecturer on Comparative Anatomy at the Middlesex Hospital. With 149 Illustrations, 8vo, 14s.

"The novel illustrations of the leading pathological processes make the work of extreme interest, and we heartily congratulate the author on the good use to which he has turned exceptional opportunities."—NATURE.

"The work abounds in careful observation, acute reasoning, and ingenious speculation. . . . . It is in our opinion the most suggestive work on general pathology which has appeared since the publication of Cohnheim's famous lectures."—DUB. JOUR. MED. SCIENCE.

"An abundance of new facts added to the pathological store."—THE LANCET.

Materia Medica: a Manual for the

Use of Students. By ISAMBARD OWEN, M.D., F.R.C.P., Assistant Physician to, and Lecturer on Materia Medica and Therapeutics at, St. George's Hospital. Second Edition, crown 8vo, 6s. 6d.

"Dr. Owen has performed a difficult task with discernment, and his work is deserving of much praise."—THE LANCET.

"Well arranged and accurate."—DUBLIN JOUR. MED. SCI.

A Practical Manual of the Diseases of CHILDREN.

With a Formulary. By EDWARD ELLIS, M.D., late Physician to the Victoria Hospital for Children. Fifth Edition, crown 8vo, 10s.

"It is in every way a book from which one who has not time to consult more exhaustive treatises may inform himself very thoroughly with reference to the cardinal points pertaining to diseases of children."—N.Y. MED. JOUR.

Cancerous Affections of the Skin: a

Treatise on Epithelioma and Rodent Ulcer. By GEORGE THIN, M.D. With 8 Engravings, 8vo, 5s.

"The sections on diagnosis and treatment are throughout sound and careful."—EDIN. MED. JOUR.

"A most excellent and masterly monograph."—GLASGOW MED. JOUR.

Clinical Lectures on Mental Diseases.

By T. S. CLOUSTON, M.D., F.R.C.P. Edin., Lecturer on Mental Diseases in the University of Edinburgh. With 8 Plates, crown 8vo, 12s. 6d.

"It is one long record of accurate and laborious observations. From cover to cover the book is positively bursting with facts."—BRAIN.

"To have read a book like this, and mastered Dr. Clouston's definitions, must make a man as well prepared as books can make him to recognise the principal symptoms of insanity."—EDIN. MED. JOUR.

Materia Medica and Therapeutics:

VEGETABLE KINGDOM; ORGANIC COMPOUNDS; ANIMAL KINGDOM. By CHARLES D. F. PHILLIPS, M.D., F.R.S. Edin., Examiner in Materia Medica in the University of Edinburgh. 8vo, 25s.

"A wonderful compilation, the materials being admirably classified and [illegible]"—Practitioner.

"Reports [illegible]"—Lond. Med. Record.

A Handbook of Diseases of the Ne

SYSTEM. By JAMES ROSS, M.D., LL.D., F.R.C.
Assistant-Physician to the Manchester Royal Infirmary.
Engravings, 8vo, 18s.

"In every part this handbook merits the highest praise,
doubt be found of the greatest value to the student as well as
tioner."—EDIN. MED. JOUR.

By the same Author.

A TREATISE on the DISEASES of the NERVOUS
Second Edition, with Lithographs, Photographs, and
2 vols. 8vo, £2 12s. 6d.

"As a complete effort to deal, in a single treatise, with
the diseases of the nervous system, this laborious work
in the English language."—THE LANCET.

Waring's Manual of Practical

PEUTICS, considered with reference to articles of
Medica. Edited by DUDLEY W. BUXTON, M.D.,
Edition, crown 8vo, 14s.

"Most useful for medical men in practice."—LOND.

"Thoroughly practical. ..... From beginning to end well
times."—THE LANCET.

"We know of no book from which the medical student
acquire a concise knowledge of practical therapeutics."—
MED. SCI.

STANDARD MEDICAL AND SURGICAL BOOKS

NEW EDITION OF GRAY'S ANATOMY.

ANATOMY, DESCRIPTIVE & SURGICAL.

By HENRY GRAY, F.R.S.,

Late Lecturer on Anatomy at St. George's Hospital.

With 569 large Woodcut Illustrations; those in the First Edition after Original Drawings by Dr. CARTER, from Dissections made by the author and Dr. CARTER. A large proportion of the Illustrations in the New Edition (the eleventh) are Coloured, the arteries being coloured red, the veins blue, and the nerves yellow. The attachments of the muscles to the bones, in the section on Osteology, are also shown in coloured outline.

Eleventh Edition, re-edited by T. PICKERING PICK,
Surgeon to St. George's Hospital; Member of the Court of Examiners, Royal College of Surgeons of England.

Royal 8vo, price 36s.

Twelfth Thousand, with 138 Illustrations Engraved on Wood, One Volume, medium 8vo, price 31s. 6d. cloth, or 42s. half-bound in russia; to be had also in Two Volumes, price 34s. cloth.

QUAIN'S DICTIONARY OF MEDICINE,

Including General Pathology, General Therapeutics, Hygiene, and the Diseases peculiar to Women and Children. By Various Writers. Edited by RICHARD QUAIN, M.D., F.R.S., &c., Fellow and late Senior Censor of the Royal College of Physicians; Member of the Senate of the University of London; Member of the General Council of Medical Education and Registration; Consulting Physician to the Hospital for Consumption and Diseases of the Chest at Brompton.

"A work of this ambitious scope, should it afford no sufficient ground for criticism, is assuredly altogether beyond the capacity of adequate review. We take leave of it by saying that, as a work, it is well conceived and well executed; that it is a really good epitome within very moderate limits, and that it cannot fail to be of use to the busy practitioner. . . . . Dr. Quain is to be congratulated upon the completion of his labours. He may rest from them in the full assurance that the result will prove a boon to the medical profession."—BRITISH MEDICAL JOURNAL.

Eighth Edition, Revised, with 964 Illustrations on Wood, Two Vols., 8vo, price 42s.

ERICHSEN'S SCIENCE AND ART OF SURGERY.

A Treatise on Surgical Injuries, Diseases, and Operations. By JOHN ERIC ERICHSEN, F.R.S., LL.D., F.R.C.S.; Surgeon Extraordinary to H.M. the Queen; ex-President of the Royal College of Surgeons. The Eighth Edition, Edited by Professor MARCUS BECK, M.S. and M.B. Lond., and F.R.C.S., Surgeon to University College Hospital, &c.

The labour demanded by a complete revision of a work extending over so wide a field as this does was greater than the author could now undertake single-handed. He therefore sought, and was fortunate in obtaining, the co-operation of his old pupil—his colleague and friend, MARCUS BECK. To him has been mainly entrusted all that relates to pathology. In those parts of the book also which relate to Clinical and Operative Surgery he has done much in assisting the author to bring up these subjects to the level of the more advanced methods of modern practice.

Third Edition, with 4 Plates in Lithography, 5 in Chromo-lithography, and 591 Wood Engravings in the Text; Three Volumes, royal 8vo, price 84s.

HOLMES'S SYSTEM OF SURGERY, THEORETICAL AND PRACTICAL.

In Treatises by Various Writers. Edited by T. HOLMES, M.A. Cantab.; Surgeon to St. George's Hospital; Membre Correspondant de la Société de Chirurgie de Paris; and J. W. HULKE, F.R.S., Surgeon to the Middlesex Hospital and to the Royal London Ophthalmic Hospital.

Third Edition, Revised by T. LAUDER BRUNTON, M.D., 8vo, price 24s.

MURCHISON'S CLINICAL LECTURES on DISEASES of the LIVER, JAUNDICE, and

ABDOMINAL DROPSY; including the Croonian Lectures on Functional Derangements of the Liver, delivered at the Royal College of Physicians in 1874. By CHARLES MURCHISON, M.D., LL.D., F.R.S., &c.; late Physician and Lecturer on the Principles and Practice of Medicine, St. Thomas's Hospital.

Ninth Edition, with 1196 Engravings on Wood, of which 97 are coloured, Two Volumes, 8vo *(which are sold separately)*, price 18s. each.

QUAIN'S ELEMENTS OF ANATOMY.

The Ninth Edition, Re-edited by ALLEN THOMSON, M.D., D.C.L., LL.D., F.R.S., formerly Professor of Anatomy in the University of Glasgow; EDWARD ALBERT SCHÄFER, F.R.S., Jodrell Professor of Physiology in University College, London; and GEORGE DANCER THANE, Professor of Anatomy in University College, London.

Complete in Three Parts, 8vo, with 12 Plates and 122 Woodcuts, price 64s. 6d. cloth.

DICKINSON on RENAL and URINARY AFFECTIONS.

By W. HOWSHIP DICKINSON, M.D.Cantab., F.R.C.P., Physician to, and Lecturer on Medicine at, St. George's Hospital; Consulting Physician to the Hospital for Sick Children; Honorary Fellow of Caius College, Cambridge; Corresponding Member of the Academy of Medicine of New York.

*** The Parts can also be had separately, each complete in itself, as follows:—Part I. Diabetes, price 10s. 6d. sewed, 12s. cloth. Part II. Albuminuria, price 20s. sewed, 21s. cloth. Part III. Miscellaneous Affections of the Kidneys and Urine, price 30s. sewed, 31s. 6d. cloth.

Twelfth Edition, Revised and Adapted to the New Pharmacopœia by NESTOR TIRARD, M.D., crown 8vo, 12s. 6d.

GARROD'S ESSENTIALS of MATERIA MEDICA and THERAPEUTICS.

By ALFRED BARING GARROD, M.D., F.R.S., Fellow of the Royal College of Physicians; Consulting Physician to King's College Hospital; late Professor of Therapeutics at King's College, London. The Twelfth Edition, Revised and Edited, under the supervision of the Author, by NESTOR TIRARD, M.D., F.R.C.P., Professor of Materia Medica and Therapeutics to King's College, London, &c.

Fourth Edition, mostly rewritten, 8vo, price 24s.

HEWITT'S DIAGNOSIS, PATHOLOGY, AND TREATMENT OF THE DISEASES

of WOMEN. Mostly rewritten. With 187 Engravings on Wood, many of which are new. By GRAILY HEWITT, M.D., F.R.C.P., Professor of Midwifery and Diseases of Women, University College, and Obstetric Physician to the Hospital; formerly President of the Obstetrical Society of London, and Examiner in Obstetric Medicine, University of London.

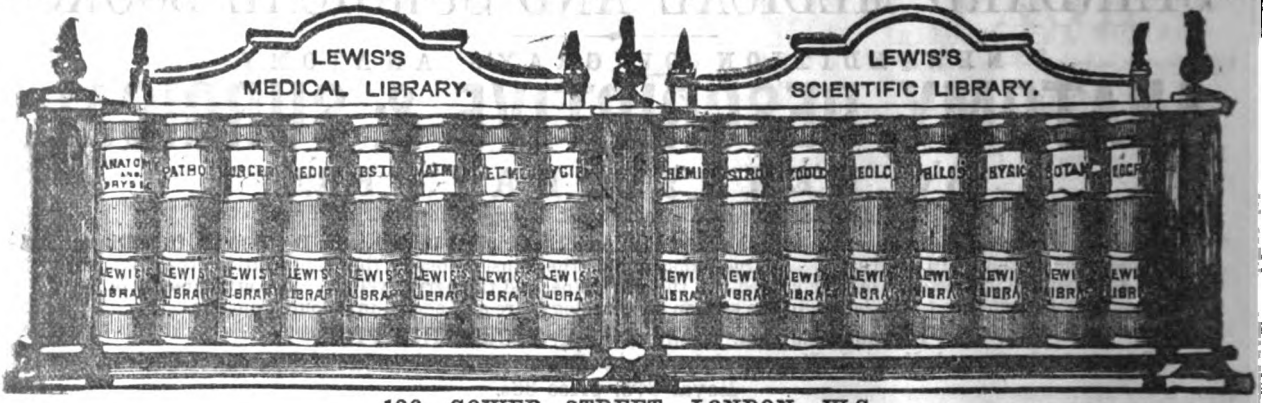
Second Edition, Revised, with 281 Illustrations, 8vo, price 6s., or Interleaved with Drawing Paper for the convenience of Students, 8s. 6d.

SCHÄFER'S ESSENTIALS of HISTOLOGY, DESCRIPTIVE and PRACTICAL.

For the Use of Students. By EDWARD ALBERT SCHÄFER, F.R.S., Jodrell Professor of Physiology in University College, London; Editor of the Histological Portion of Quain's Anatomy.

"This book contains all that a student of histology, physiology, or pathology needs to know."—THE LANCET.

Fourth Edition, thoroughly Revised, with 120 Illustrations engraved on Wood, fcap. 8vo, price 5s.



ASHBY'S NOTES ON PHYSIOLOGY FOR THE USE OF STUDENTS PREPARING

for EXAMINATION. By HENRY ASHBY, M.D.Lond., Physician to the General Hospital for Sick Children, Manchester.

London: LONGMANS, GREEN, & CO.

London: Smith, Elder, & Co., 15, Waterloo-place.

NEW EDITION OF FINLAYSON'S "CLINICAL MANUAL."
Second Edition, Revised and Enlarged, with many New Illustrations, crown 8vo, 12s. 6d.

Clinical Manual for the Study of

MEDICAL CASES. Edited by JAMES FINLAYSON, M.D., Physician and Lecturer on Clinical Medicine in the Glasgow Western Infirmary. With Special Chapters by Prof. GAIRDNER on the Physiognomy of Disease; Dr. ALEXANDER ROBERTSON on Insanity; Dr. JOSEPH COATS on the Throat; Professor STEPHENSON on Disorders of the Female Organs; Dr. SAMSON GEMMELL on Physical Diagnosis.

"The appearance of a new edition of this very complete guide to clinical investigation is significant of the increased attention that is being paid to practical study and ward work. The volume before us has the merit of being contributed to by several physicians, and is consequently thorough in its treatment of the various subjects .... The student could hardly wish for better guides, and the manner in which the subjects are dealt with proves the high standard of excellence in clinical teaching at Glasgow."—THE [illegible]

DISEASE AND SIN.

A NEW TEXT-BOOK FOR MEDICAL AND DIVINITY STUDENTS.

By a MEDICAL MUSER.

"It is a long time since we read such a thoroughly unconventional book.....He writes like an able physician and a thorough-going philanthropist.....Altogether, we heartily praise the book. On every page there is something to make one think."—GRAPHIC.

"The anonymous author of this remarkable book is evidently a medical man.....We may conclude by saying that any man (for the work is written for men only) will, after reading it, see many things in new and striking lights, and certainly be set a-thinking as he never thought before."—SCHOOLMASTER.

"Should be the means of effecting much good amongst young men, not only of this, but of future generations."—CITY PRESS.

"We have not come across a book for a long time which we like so well."—HAMPSHIRE TELEGRAPH.

"This is quite a unique work. It is fresh, original, scholarly, impressive. ..... Religious teachers of all schools of thought will revel in this treatise."—OLDHAM CHRONICLE.

"This is a remarkable book. ..... It has a gospel for the age. We wish it a large audience."—PRESBYTERIAN CHURCHMAN.

SLINGER'S NUTRIENT SUPPOSITORIES.

Consisting of nearly pure Peptone and Extractive from the Artificial Digestion of Meat. Five Suppositories contain the Extractive of 20 ounces of Meat, in addition to the Peptone. R. H. BOUCHIER NEWBOLSON, Esq., Hull Infirmary, in a case of Gastrostomy, says:—"The beef suppositories (made by SLINGER & SON, York) were of much benefit, the man saying he felt great comfort from their use. The man was saved the pangs of starvation, from which he was fast sinking when I first saw him." Manufactured only by SLINGER & SON, Wholesale Druggists, York. Wholesale Agents: Messrs. NEWBERY & SON, 1, King Edward-street, Newgate-street, London, E.C.

CIMOLITE (Gr. κιμωλια)

Terra Cimolia (popularly known as "WHITE FULLER'S EARTH"). A fine and very scarce natural variety of Steatite, composed principally of Silicate of Magnesium, and reduced by the most careful trituration and sifting to the FINEST POSSIBLE POWDER.

Highly recommended by the most eminent Dermatologists. As a Dusting Powder in Eczema it is simply invaluable, and is infinitely superior to Oxide of Zinc, Prepared Calamine, Carbonate of Bismuth, Powdered Starch, or any other Amylaceous Compound; also in all cases of Infantile Chafing, for most Irritations of the Skin, and all Excoriations. For the Profession *only*, in Tins, free per post, send 18 penny stamps. For the general public, post free, send 14 or 36 penny stamps.

Introduced into medical practice and prepared by John Taylor, Chemist (many years with Squire, Oxford-street), 13, Baker-street, Portman-square, London, W.

ROBERTS & CO., 76, New Bond-street London.

CIGARS DE JOY

One of these Cigarettes gives IMMEDIATE RELIEF in cases of ASTHMA, CHRONIC BRONCHITIS, HAY FEVER, INFLUENZA, COUGH, and SHORTNESS OF BREATH, and their daily use effects a COMPLETE CURE. The contraction of the air tubes, which causes tightness of chest and difficulty of breathing, is at once lessened by inhaling the medicated smoke of the Cigarette; a free expectoration ensues, and the breathing organs resume their natural action. Persons who suffer at night with COUGHING, PHLEGM, and SHORT BREATH find them invaluable, as they instantly check the spasm, promote sleep, and allow the patient to pass a good night.

These Cigarettes are perfectly harmless, and can be smoked by ladies, children, and the most delicate patients, as they are pleasant to use, and contain no substance capable of deranging the system.

NONE GENUINE UNLESS SIGNED ON BOX. H. W. WILCOX.

SOL. MORPH. BIMEC.
(SQUIRE.)

This preparation, introduced by Peter Squire in 1839, is prepared direct from Opium by a process of elimination. It differs considerably from a solution of the salt, which is made by dissolving Morphia in a solution of Meconic Acid.

It is therefore necessary for prescribers to indicate SQUIRE'S when they wish to order this old-established preparation.

COMPAGNIE FERMIÈRE DE L'ÉTABLISSEMENT THERMAL DE

ALLIER,] VICHY [FRANCE.

(Property of the French State.)

NATURAL MINERAL WATERS OF VICHY.

(STATE SPRINGS.)

CELESTINS.—A famous remedy for Kidney Disease, Gravel, Gout, Rheumatism, Diabetes, &c.

HAUTERIVE.—Strongly impregnated with natural Carbonic Acid, which renders it very fit for EXPORT. An excellent TABLE WATER, invaluable for Dyspepsia.

GRANDE-GRILLE.—For Diseases of the Liver and Biliary Organs, &c.

HÔPITAL.—For Stomach Complaints, Indigestion, &c.

The VICHY WATERS are remarkable for their keeping qualities, and even after a great lapse of time the alteration that takes place is inconsiderable. They form an agreeable beverage, whether mixed with wine or spirits or taken alone. They are bottled under the supervision of GOVERNMENT OFFICIALS, thus giving a PERFECT GUARANTEE of their GENUINE CHARACTER.

The VICHY WATERS are recommended and used by the greatest Medical Authorities.

When Prescribing VICHY WATERS, state the Spring required.

Woodhall Spa. Bromo-Iodine Mineral Water.

The strongest known Mineral Water in the world. This remarkable Spa has been purchased by a syndicate of gentlemen, who have determined to make more widely known the extraordinary curative powers of this Spring, which contains more Iodine and Bromine than any Spring in Europe.

An analysis of the water having been made in November, 1886, by Professor Wanklyn, M.R.C.S., corresponding member of the Royal Bavarian Academy of Sciences, Professor of Chemistry, a very important discovery has been made—viz., the presence of Free or Elementary Iodine.

Prof. Wanklyn says:—"So far as I am aware, this is the first instance in which free Iodine has been found in appreciable quantity in a natural water. For many years the Woodhall Spa has been celebrated as a valuable remedy in skin diseases. The fact that it is a solution of free Iodine is interesting in this connexion, and well worthy of the attention of t he medical profession."

The Woodhall Bromo-Iodine Water is now being bottled at the Spring by the Sole Agents. BROMLEY & CO., Chemists, 233, High-street, Lincoln, 5 and 6, The Grove, Buxton, and Woodhall. All communications to be addressed to them at the Spa, Woodhall, Horncastle.

ROBINSON'S CONCENTRATED WATERS

One Ounce of these Waters added to Forty Ounces of Distilled Water forms a clear Medicated Water (without filtering), similar in every respect to those prepared according to the directions of the British Pharmacopœia, and free from all Chemical Impurity. They are prepared to supply a want long felt by Chemists and Medical Men, and by their use a fresh supply of any of the Medicinal Waters may be obtained at a moment's notice. They are not affected by age in any climate. N.B.—Used in the proportion of one part to thirty-two of water, they represent the Medicinal Waters of the *United States Pharmacopœia*.

	Per lb.		Per lb.		Per lb.		Per lb.

"THE BEST NATURAL APERIENT."

Persistent attempts are made by interested parties to deceive the public by offering Natural Mineral Aperient Waters with marks, names, and designations very similar to those which are used by the **APOLLINARIS COMPANY, LIMITED**, for the **NATURAL MINERAL APERIENT WATERS** imported by them.

Under these circumstances the **APOLLINARIS COMPANY, LIMITED**, feel compelled to caution the public that the **HUNGARIAN BITTER WATER** sold by the **COMPANY** always bears the name of the **APOLLINARIS COMPANY, LIMITED**, on the Label.

NATURAL MINERAL WATERS OF BUSSANG—"VOSGES."

HIGHLY TONIC AND RESTORATIVE.

Bicarbonated, Alkaline, containing Salts of Iron, Manganese, Arsenic, and Lithia, intimately combined with Carbonic Acid Gas. A sovereign remedy in Chlorosis, Anæmia, Gastralogy, Dyspepsia, Chronic Diarrhœa, Vesical Catarrh, Renal Colic, Gravel, and Gout. Its "Anti-Lithique" action is demonstrated by the fact that it reduced to a fine powder a calculus which had been submerged in it for a month, and instead of producing the debilitating effects of purely Alkaline Water, it has the inestimable virtue of entirely eliminating the uric acid and fortifying the stomach. It is a valuable adjunct in the treatment of Bright's Disease, Diabetes, and noted in all cases of Convalescences, and as a preservative from epidemic and infectious maladies.

F. E. STURMFELS, 25, Coleman Street, London, E.C.

SPA LANGENSCHWALBACH (in the "Taunus"), Germany.

Gubernatorial District of Wiesbaden, 300 metres above the level of the sea; two hours from the railway stations, Wiesbaden, Ems. Strongest among the pure ferruginous spring of Germany, large contents of carbonic acid, richly-wooded environs, refreshing mountain climate. Drinking Springs, Wine, and Chalybeate Waters. Chalybeate and Moor Baths in the Royal Bathing House and in private establishments. Efficacious against Want of Blood, its consequences and complications; Nervous Diseases, Female Complaints, Debility of the Muscles, Lameness, Catarrhs of the Mucous Membranes, especially of the Sexual and Urinary Organs. Entertainments: Kursaal, Reading Rooms, Concerts, Réunions, Excursions to the Rhine, Aar Valley, Whisper Valley, &c. Lodgings in hotels, and in more than 100 villas and lodging-houses. Post, telegraph, custom-house, banking-houses, American Consular Agency. First-class hotels: Allcesaal, Herzog von Nassau, Metropole, Quellenhof, Hotel Taunus.—For information apply to the Städtische Kurverwaltung. Opening of the season on 1st of May.

BADEN-BADEN.

Old-renowned alkaline chlor. sod. springs of 44—69° C. Chlor. lithium spring of preponderous contents.

New Grand-ducal Bathing Establishment "THE FREDERIC BATHS."

OPEN THROUGHOUT THE WHOLE YEAR.

A model institution, unique for its perfection and elegance. Tub-baths, Russian vapour baths, Turkish baths, electric baths, so-called "*Wildbäder*" (thermal water constantly running), swimming baths, rooms for cold-water treatment, inhalation of pulverised mineral water, douches for the larynx, douches of all forms and temperature, medicinal baths of every description. Private Medical Institutions with thermal baths. Pump-room with the mineral waters of all the most renowned springs, whey- and milk-cures, spring-cures with the juice of herbs, autumn-cures with excellent grapes. Pneumatic Establishment with two chambers for four persons each. Establishment for physical treatments. Expedition of the mineral water of preponderous contents of lithium.

Conversation House with its splendid Concert-, Ball-, and Reading-rooms, Restaurant and Society-rooms open throughout the whole year. Grand Concerts, Symphonie- and Quartetto-soirées, Special Concerts by renowned artists. Bals parés, réunions. Children's festivals. Splendid Orchestra (48 musicians) with solo players, three concerts daily. Military concerts. Operas and comedies. Fireworks and illuminations. Shooting and fishing. Grand races. Educational institutions of high order.

BADEN-BADEN, surrounded on all sides by luxuriant pine and beech woods, offers opportunities for the most charming walks and excursions Excellent climate. Charming situation. Mean annual temperature: +7, 4° R.

The Natural Salt of the HOMBURG ELIZABETH SPRING

This Salt is obtained from the NATURAL Water, and has all the properties of the Natural Spring, which are so efficient in cases of Gout.

BROMIDIA.

FORMULA.—Every fluid drachm contains 15 grs EACH, of pure Brom. Potas. and purified Chloral, and 1-8 gr., EACH, of gen. ext. Cannabis Ind. and Hyoscyam.

DOSE.—One-half to one fluid drachm in WATER or SYRUP every hour until sleep is produced.

BROMIDIA IS THE HYPNOTIC PAR EXCELLENCE.

It produces refreshing sleep, and is exceedingly valuable in sleeplessness, nervousness, neuralgia, headache, convulsions, colics, &c., and will relieve when opiates fail. Unlike preparations of opium, it does not lock up the secretions. In the restlessness and delirium of fevers it is absolutely invaluable.

Is sold in 4 oz. Bottles at 40s. per dozen; 12 oz. Bottles at 108s. per dozen.

BATTLE & CO., St. Louis.

General Depot for Great Britain:—ROBERTS & CO. 76, New Bond Street, W.

TAMAR INDIEN GRILLON.

A laxative, refreshing, and medicated Fruit Lozenge, very agreeable to take, and never causing irritation. Its physiological action assures the immediate relief and effectual cure of

CONSTIPATION,

HÆMORRHOIDS, BILE,
CEREBRAL CONGESTION, HEADACHE,
LOSS OF APPETITE,
INTESTINAL OBSTRUCTIONS, &c.,

By augmenting the peristaltic movement of the intestine without producing undue secretion of the liquids. Unlike pills and the usual purgatives it does not predispose to intestinal sluggishness, and the same dose always produces the same effect, that is to say, never needs increasing.

It is recommended by the most eminent Physicians of Paris, notably Drs. BERLIN and TARDIEU, who prescribe it constantly for the above complaints and with most marked success.

Wholesale—London: E. GRILLON, 69, Queen Street, Cheapside.

Sold by all Chemists and Druggists, 2s. 6d. a box stamp included.

TONGA.

A SPECIFIC FOR NEURALGIA.

TONGA is the name given to a remarkable remedy for Neuralgia. It is a fluid extract of a special combination of the Barks, Roots, and Leaves of several plants, the peculiar efficacy of which was discovered by a resident in the South Pacific whilst seeking relief from intense Neuralgia. The drug was first introduced to us during the summer of 1879. On submitting it to a trial, it was at once found by competent medical authorities to possess extraordinary power in relieving Neuralgic pains. (See papers in THE LANCET of March 6th and 20th, and May 29th, 1880, by Dr. MURRELL, Dr. RINGER, Dr. LUSH, and C. BADER, Esq., for the record of severe Neuralgic pains removed by the use of TONGA.)

"Tonga maintains its reputation in the treatment of Neuralgia."—THE LANCET, July 23rd, 1881.
"Invaluable in facial Neuralgia."—MEDICAL PRESS AND CIRCULAR, Dec. 29th, 1880.
"Has proved effective in all those cases of facial Neuralgia in which we have prescribed it. It is an elegant and easily-taken remedy."—MEDICAL PRESS AND CIRCULAR, Jan. 26th, 1881.

Extract from a Letter in the BRITISH MEDICAL JOURNAL, March 26th, 1881.

"After trying quinine, arsenic, iron, morphia, and the pills above mentioned (gelseminum, croton-chloral-hydrate and monobromide of camphor) Tonga was used, and the effect was almost instantaneous. "I am, &c., KENNETH W. MILLICAN, B.A., L.R.C.P.ED."

TONGA, unlike opium and other anodynes, produces its remarkable specific action on the nerves without giving rise to any derangement of the digestive or other organs.

DOSE: From half to one Teaspoonful in water three times a day. Relief generally follows the third or fourth dose. N.B.—No ill effects follow from larger doses.

PAPAIN (FINKLER). THE NEW DIGESTIVE FERMENT.

USES.—INTERNALLY: In Dyspepsia and Gastralgia. Geo. Herschel, M.D. Lond., writes in the *British Medical Journal*, April 3rd, 1886:—"I find it chiefly valuable in (1) the Chronic Stomach Catarrhs of Children, (2) Acid Dyspepsia, and (3) Severe Gastric Pain coming on shortly after eating."

EXTERNALLY: It has been used by *Bouchut* in *cutaneous carcinoma*, *Rassbach* for dissolving the false membranes of *Diphtheria* (see *Zeitsch. für Klin. Med.*, vi., H. 6), by *Jacobi* of New York for the same purpose, and recently Prof. Finkler himself has restored patency to an œsophagus occluded by *carcinoma* by the continuous administration of a solution.

Manufactured by Dr. FINKLER & CO., Godramstein (Palatinate).

Sole Agent for the United Kingdom and Export—

B. KÜHN, 36, St. Mary-at-Hill, London. 55, Bloom-street, Manchester.

Supplied by all Wholesale Druggists.

DUSART'S SYRUP AND WINE
OF
LACTO-PHOSPHATE OF LIME.

The properties of Lacto-Phosphate of Lime are scientifically founded on physiological experiments, and for many years it has received the approval of the leading members of the Medical Profession as the most valuable reconstituent of the tissues and bones IN ALL CASES OF CACHEXIA OR ADYNAMIA where nutrition is impaired by acute or chronic complaints.

LACTO-PHOSPHATE OF LIME only differs from PHOSPHATE OF LIME (the natural restorer of muscular fibre and bone) by being made assimilable by the action of its natural solvent, lactic acid.

It acts as a general excitant of the nutritive functions, ensures digestion, restores the appetite, enriches the milk of the mother, and improves all the vital energies. In convalescence, teething, rickets, and imperfect growth it is especially useful; whilst wounds, fractures, and all affections of the osseous system are rapidly benefited by its use.

DUSART'S SYRUP OF LACTO-PHOSPHATE OF LIME AND IRON is invaluable where any of the above cases are complicated by chloro-anæmia.

Dose—For Adults, 3 to 6 tablespoonfuls a day; for Children, 3 to 6 dessertspoonfuls.

MIDY'S CAPSULES OF PURE SANDAL WOOD OIL.

Each Capsule contains 4 grains of the purest distilled ESSENCE OF SANDAL. They have been adopted in the Paris hospitals in place of copaiba and cubebs on account of their inoffensive nature, even in strong doses. Complete relief is obtained within forty-eight hours, and the discharge (whatever the abundance or colour of the secretion) is reduced to a few drops of white muco-pus, which ultimately disappears altogether. MIDY'S PURE SANDAL causes neither indigestion, repulsive eructation, nor diarrhœa, and the urine is free from smell. Dose—10 to 12 Capsules.

CHAPOTEAUT'S PEPSIC-PEPTONES.

PEPTONE POWDER.—Being quite soluble, neutral, and pure, it affords nourishment to patients without the addition of any other aliment; two tablespoonfuls contain 10 grammes of Peptone, and represent 60 grammes of lean beef. It can be taken in tea or broth.

PEPTONE WINE.—Each claret glassful contains 10 grammes of lean meat, and is recommended in anæmia, diabetes, during convalescence, and to persons in reduced health and suffering from loss of appetite, distaste to food, or from gastritis or gastralgia.

CHAPOTEAUT'S PURE DIALYSED PEPSINE PEARLS.

These contain each 4 grains of absolutely pure Pepsine, the digestive powers of which are 100 times its weight of solid meat.

CHAPOTEAUT'S MORRHUOL.

MORRHUOL contains all the active principles of Cod-liver Oil with the exception of the fatty matters. It is dispensed in small round capsules, each containing 20 centigrammes, equal to twenty-five times its weight, or 5 grammes of brown Cod-liver Oil.

PRINCIPAL EFFECTS.—Increase of Appetite—Abatement of Cough—Regulation of the Digestion and of the Bowels—Return of Strength and of Sleep.

THERAPEUTIC USES:—Bronchitis—The First Stage of Tuberculosis—Rickets—Scrofula—Diseases of the Lymphatics.

DOSES:—For CHILDREN, two to four capsules daily at meal times. For ADULTS, four to eight capsules.

London: WILCOX, 289, Oxford St.; NEWBERY & SONS, 1, King Edward St.
Wholesale: Paris, GRIMAULT & CO., 8, Rue Vivienne.

PERFECTION IN SOLUBLE PILLS AND GRANULES.

Highest and only Award for Pills at International Medical and Sanitary Exhibition, South Kensington, London, 1881.

Only Award, Brighton Health Congress and Sanitary Exhibition, 1881.

Numerous Gold and Silver Medals.

Large reduction in price. See Price List.

These Pills and Granules are in Tasteless Transparent Coating, Unequalled for Purity in Composition, Solubility in Coating, Uniformity in Size, Perfection in Form and Finish,

MANUFACTURED BY

W. H. SCHIEFFELIN & CO.,

Who desire to call the attention of Physicians and Pharmacists to the following points:—

1. The best materials are used in their manufacture.
2. The Pills are Coated while soft.
3. The Coating is quickly and perfectly soluble, and there is no subcoating of any kind.
4. The Coating is so thin that the Pills are not perceptibly increased in size, and yet entirely protects them and effectually covers any nauseous taste.
5. The Coating is so transparent as to clearly reveal the colour of the mass, and its solubility is not impaired by age.
6. The mass is worked to the highest possible degree of uniform intermixture, and subdivided with scrupulous exactness.
7. Vegetable or organic matters are not charred, nor are volatile principles lost by the use of heat at any time throughout the process of manufacture.
8. The excipients are specially adapted to the permanent solubility of the mass and its efficient therapeutic action.

SELECTED FORMULÆ OF PILLS.

ALOIN STRYCHNIÆ ET BELLADONNÆ PIL.

Aloin,	1-5 gr.
Strychniæ,	1-60 gr.
Ext. fol. Belladonnæ,	1-8 gr.

(Dose: 1 Pill.)

CALCII SULPHIDI PIL., 1-10 gr., ½ gr., ¼ gr., 1 gr. (Dose: 1-10 to 1 gr.)

This salt, which under ordinary circumstances rapidly spoils, keeps well in the soluble coated pill.

CASCARÆ SAGRADÆ EXTRACT. Pil., 2 grs.

(Dose of the Extract: as a Laxative, 3 to 4 grains; as a Cathartic, 6 to 14 grs.)

EUONYMIN ET COLOC. COMP. EXT. PIL.

Euonymin,	1 gr.
Coloc. Comp. Ext., P.B.,	3 grs.

(Dose: 1 Pill.)

FERRUGINOUS (Blaud's) PIL.

Ferri Sulph.,	2½ grs.
Potass. Carb.,	2½ grs.

(Dose: 1 to 3 Pills.)

These pills are admirably adapted for the assimilation of iron, as the ingredients react upon each other to form protoxide of iron, which, owing to the protection afforded by the soluble coating, remains unaltered until freed for action by the stomach juices.

PHOSPHORI PIL., 1-100 gr., 1-50 gr., 1-33 gr., 1-25 gr., 1-20 gr.

(Dose: 1-100 to 1-20 gr.)

In our pills the Phosphorus is incorporated with the other ingredients while in solution so as to effect a uniform and thorough diffusion. The Phosphorus is perfectly protected from oxidation, which may be readily ascertained by cutting one of the pills however long it may have been kept. At the same time the excipients with which the Phosphorus is mixed sufficiently dilute the mass to prevent the degree of irritation which is liable to follow when a mass strongly charged with Phosphorus comes in contact with the mucous surfaces. Hence the several Phosphorus Pills, though each containing small and different quantities of the active ingredient, are all of a medium size.

WARBURG'S TINCTURE (representing one drachm each).

(Dose: 1 Pill.)

There is so much testimony as to the extraordinary virtues of Warburg's Tincture in Malarial Fevers that its powers can scarcely be questioned. At first a proprietary medicine, its formula was afterwards revealed by a voluntary act of its inventor, Dr. CARL WARBURG, late of Vienna, but now of London, U.S.D., 1883.

Ours is prepared in accordance with the original formula, except that Confection of Theriac, Ph.G., is substituted for Confection Damocratis—an unofficinal and impracticable preparation, some ingredients of which are nowhere obtainable. The pill form is the most eligible for its administration, as it may be so taken without offence to the palate.

The attention of Physicians is respectfully called to the following formula, which has justly merited the approval of the profession, wherever presented, and which we think is worthy a trial.

PIL. QUINIÆ, FERRI ET ZINCI VALERIANAT.

Quiniæ Valerianat.,	1 gr.
Ferri, ,,	1 gr.
Zinci, ,,	1 gr.

Editor MEDICAL BRIEF, St. Louis, Mo., U.S.A.

"The family doctor only knows how widespread Melancholia is in our country. The many household cares develop this disease in nervous women, who show its first symptoms in fretfulness and worry. I have sought for a remedy for years for this malady, and have at last found it in the triple valerianates, which work like a charm."

"ERGOTIN" (EXT. ERGOTÆ) Pil., 1 gr., 3 grs. (Dose: 1 to 6 grs.)

The demand for our "Ergotin" Pills has been very great. We have manufactured for a long time this "Ergotin," which is more properly speaking a carefully prepared aqueous extract.

The "Ergotin" of the market is of several kinds, and generally unreliable.

Our 3-grain pill effectually represents 15 to 17 grains of Ergot.

Private Formulæ made and coated in quantities of 2000 and upwards.

Price List of Pills and Book of about 400 useful Formulæ (including those of the British Pharmacopœia) sent free on application to

W. J. BUSH & CO.'S
ENGLISH SANDAL WOOD OIL.

ABSOLUTELY PURE AND ALWAYS UNIFORM.

DR. HENDERSON, of Glasgow, writes:—"It is a pure Oil of a high character. I have tried it in numerous cases of Gonorrhœa. It was rapidly successful in all. The Oil disagreed with no one."

THE LANCET states:—"It is admirably adapted for use as a medical agent."

The BRITISH MEDICAL JOURNAL states:—"It is unusually *free* from disagreeable taste."

The CHEMIST AND DRUGGIST states:—"The fact that Dr. Henderson speaks highly of this Oil is the best proof of its therapeutic activity."

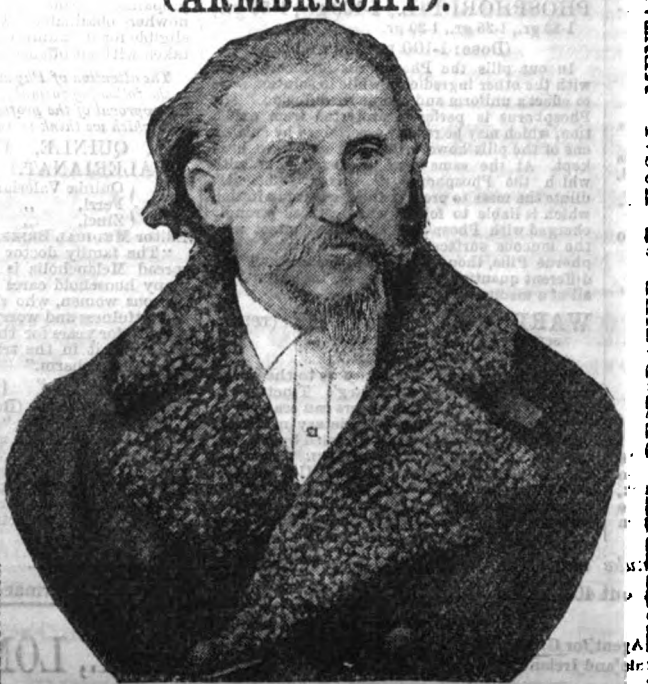
ARTILLERY LANE, BISHOPSGATE, LONDON, E.C.

HOUDÉ'S PASTILS
WITH CHLORHYDRATE OF COCAINE.

Through the insensibility which they produce, our *pastils with chlorhydrate of cocaine* procure the greatest relief and soothe the pain in sickness of the throat, in hoarseness, extinction of the voice, laryngitis, inflammation of the throat, and asthmatic complaints.

They contribute to do away with the pricking and titillation of the throat, and strengthen the vocal cords, also a very useful agent in the diseases of the œsophagus and the stomach, sea-sickness, gastritis, gastralgia, vomiting, &c.

Dose.—Take 6 to 8 pastils per diem, according to age, and at least one hour before meals.



Per Box 2s. 9d. post free; gratis to Members of the Profession.

Depot.—A. HOUDÉ, late Vee & Duquesnel's Pharmacy,
42 Rue du FAUBOURG ST. DENIS, PARIS, AND ALL CHEMISTS.

HORSFORD'S ACID PHOSPHATE,

(LIQUID.)

Prepared according to the directions of Prof. E. N. HORSFORD, of Cambridge, Mass., U.S.A.

FORMULA:—Its analysis shows that each fluid drachm contains 5 1-2 grains free Phosphoric Acid (P_2O_5), and nearly 4 grains Phosphate of Lime, Magnesia, Iron, and Potash.

Horsford's Acid Phosphate has been in use by the medical fraternity of America and elsewhere for many years, with the most satisfactory results, in

Dyspepsia, Indigestion, Mental and Physical Exhaustion, Insomnia, Nervousness, Diminished Vitality, &c.

It is a colourless liquid, acid to the taste, and contains no pyro-phosphate or meta-phosphate of any base whatever.

Among the numerous forms of phosphorus in combination, Horsford's Acid Phosphate seems best adapted for use as a medicinal remedy.

Especially serviceable as a menstruum for the administration of such alkaloids as strychnia, morphia, quinia, and other organic bases which are usually exhibited in acid combination.

It makes a refreshing and nutritious drink in fevers, and with water and sugar a delicious beverage.

Cable Address—"RUMFORD, PROVIDENCE." RUMFORD CHEMICAL WORKS—Providence, R.I., U.S.A.

CAN BE OBTAINED FROM

☞ **PHYSICIANS** who have not used Horsford's Acid Phosphate, and who wish to test it, will be furnished a sample on application to Corbyn, Stacey, & Co., Francis Newbery & Sons, Barclay & Sons, London; James Woolley, Sons, & Co., Manchester; or John Thompson, Liverpool; and sample will be furnished free of charge, except the expense of packing and postage (sevenpence), which amount should accompany the application.

MALTOPEPSYN.

That many of the diseases from which mankind suffer during infant and adult life are caused by malnutrition, there can be no doubt; and the extent to which non-assimilation of the life-giving properties of food interferes with recovery from severe illness, baffling the best directed efforts of the physician, points to the necessity for an agent or combination of agents sufficiently potent to replace the deficient principle and aid nature in renewing the degenerated tissues.

Realising this need, the science of chemistry produced *Pepsine*. Of this remedy RICHARD TUSON, F.C.S., Professor of Chemistry, London, speaks through the August 13th, 1870, number of THE LANCET as follows:—

"Since the introduction of Corvisart and Boudault's poudre nutrimentive into medicine in the year 1854, Pepsine obtained from the stomach of the pig, calf, or sheep, in a state of greater or less impurity, has been extensively prescribed in Dyspepsia and certain other affections. According to the testimony of some authorities of high standing, long experience in the use of this agent fully justifies Corvisart's predictions relative to its therapeutic value, which were based on physiological reasoning. There are other authorities, however, who express doubts as to the efficacy of Pepsine.

"This difference of opinion undoubtedly arises from the circumstance that pharmaceutists supply medical men with various preparations, all bearing the same specific name of Pepsine, but differing very considerably in their digestive powers and other qualities. In fact, I find those who speak favourably of its employment in the treatment of diseases have prescribed that prepared by the best makers; while those who express a doubtful opinion have been in the habit of prescribing those varieties or makes which the experiments of myself and others have proved to be practically without any digestive activity"—i.e., *worthless*.

Under these circumstances it is *absolutely* necessary for the practitioner to be certain of the *make* of Pepsine he uses. *Pure* Pepsine, thoroughly triturated with finely-powdered sugar of milk (saccharated pepsine), will undoubtedly produce the best results. Experience in diseases of the stomach, Dyspepsia, &c., has demonstrated in many cases the lack of other agents required to promote a healthy digestion besides Pepsine—namely, Pancreatine and Diastase, or vegetable Ptyalin. Pancreatine, the active principle of the sweetbread or pancreas, possesses the wonderful power of emulsifying the fats and oils of food, rendering them easy to assimilate, and which are not affected by Pepsine in the slightest degree. Diastase, or vegetable Ptyalin, as obtained from malted barley in the *dry* extract of malt, represents the saliva, and has the remarkable property of converting the insoluble starchy portions of food into the soluble glucose, thus rendering the said indigestible and innutritious article—starch—into the nutritive and easily assimilated food, glucose.

The value of these different ingredients, and the difficulty of procuring them of the right quality, led Hazen Morse, chemist, late of Toronto, now of Ontario, Canada, to experiment with various combinations, during seven years' employment in the manufacture of Pepsine, on a large scale; and, with the assistance of several prominent physicians, he was finally enabled to present to the profession the following formula:—

Saccharated Pepsine	10 grains.
,, Pancreatine	5 ,,
Acid Lacto-phosphate of Lime ...	5 ,,
Exsiccated Extract of Malt equal to one teaspoonful of Liq. Ext. of Malt	10 ,,

and registered it at Ottawa, Canada, and London, England, under the distinctive name

MALTOPEPSYN,

thus giving the physicians a guarantee of always procuring the same standard preparation and preventing their being imposed upon by imitations of inferior quality, at the same time putting it at as *low a figure* (2s. 9d. for 1 ounce) as possible for such a formula to be compounded, using the ingredients of the *best possible* make.

Maltopepsyn has digestive power *ten times* greater than the best Pepsine in the market, as it digests Fibrine and Caseine, emulsifies the fat of food taken into the stomach, thus rendering it assimilable, converts starch into glucose; in fact, it combines all the agents that act upon food, from mastication to its conversion into chyle, digesting all aliment used by mankind, while Pepsine acts only on plastic food. Maltopepsyn also combines with the above the nutritive qualities of Extract of Malt, and the brain- and nerve-strengthening powers of the Acid Phosphates.

LIQ. PODOPHYLLIN (HOCKIN).

Miscible (bright) in Aquos, Acids, or Alkaline Solutions, also with Decoctions, Ethers, Infusions, Tinctures, &c.

These preparations contain no colouring matter whatever.
Each Drachm is equal to Podophyllin Pur. ¼ grain.

The BRITISH MEDICAL JOURNAL, Feb. 12th, 1887, says:—

"Although the value of Podophyllin as a cholagogue has long been recognised, much difficulty has been experienced in prescribing it in a liquid form. Many patients cannot take pills, and prefer having a mixture. The new preparation contains a quarter of a grain in a drachm, and is miscible not only with water, acid, and alkaline solutions, but also with infusions and tinctures. It is active in very small doses, and undoubtedly supplies a long-felt want."

The MEDICAL PRESS and CIRCULAR, March 30th, 1887, says:—

"Owing to its insolubility, podophyllin is mostly exhibited in the form of pill; and, as a consequence, occasionally passes through the intestinal canal more or less unabsorbed, and to the disappointment both of patient and physician. This liquor contains one-quarter of a grain of podophyllin to the drachm, and when added to water produces a clear solution the colour of sherry, and without any precipitation of the drug. In cases of dyspepsia occasioned by torpidity of the liver, I have obtained excellent results from the administration of a drachm of this liquor in an ounce of gentian mixture two or three times a day. From two to four drachms of the liquor, together with an ounce of decoction of aloes and five minims of tincture of capsicum, form a good cholagogue aperient."

The EDINBURGH MEDICAL JOURNAL, April, 1887, says:—

"LIQ. PODOPHYLLIN (HOCKIN). Prepared only by HOCKIN, WILSON, & Co., London.—This is an excellent preparation, containing two grains of podophyllin in every fluid ounce, and one which we can recommend to the notice of the profession."

LIQ. PODOPHYLLIN ET PEPSIN (HOCKIN).

A Soluble Preparation of Podophyllin and Pure Pepsin. Of great Digestive Power.

DOSE:—One Drachm.

LIQ. PODOPHYLLIN ET BELLADONNA C. STRYCHNIA (HOCKIN).

(*Synonymous* **LIQ. HOCKIN**).

EACH DRACHM EQUALS—

Podophyllin Resin	**1-4 gr.**
Ext. Belladonna Rad. Alch.	**1-8 ,,**
Strychnia	**1-30 ,,**

Acts most beneficially in torpid liver from defective nerve-influence, and also upon the alimentary canal. It increases the tone and vascularity of the stomach, improves appetite and promotes digestion, and in atonic dyspepsia, and various chronic catarrhal affections of the gastric mucous membrane it acts as an excellent tonic, greatly increasing the muscular contractions of the intestinal tube, and counteracts constipation and fæcal accumulations.

PRICE (for Dispensing), 16 oz. bots., 7s.; 8 oz. bots., 4s.; 4 oz. bots., 2s. 6d.; Winchester qts., 6s. 9d. per lb.
All bottles and packing free, postage only charged, as follows:—16 oz. bots. 6d., 8 oz. bots. 6d., 4 oz. bots. 3d. extra.

BENGER'S FOOD

(*PANCREATISED*)

FOR

INFANTS,

CHILDREN,

AND INVALIDS.

GOLD MEDAL—International Health Exhibition, London.

"*Mr. Benger's admirable preparations.*" — THE LANCET, March 25th, 1882.

"*Deserving of the highest praise, and only require to be made known to the profession to ensure their extensive employment.*"—THE PRACTITIONER, February, 1883.

"*Few modern improvements in pharmacy have done so much as Benger's Preparations to assist the physician in his treatment of the sick.*"—THE MEDICAL PRESS, June 13th, 1883.

"*Benger's Preparations have deservedly a very high reputation, and are all largely used.*"—THE MEDICAL TIMES AND GAZETTE, September 8th, 1883.

"*Undoubtedly a great advance on any previous attempt in this direction. It is palatable and excellent in every way. We have given it in very many cases with the most marked benefit, patients frequently retaining it after every other food had been rejected. For children who throw up their food in curdled masses it is invaluable.*"—THE LONDON MEDICAL RECORD, March 15th, 1882.

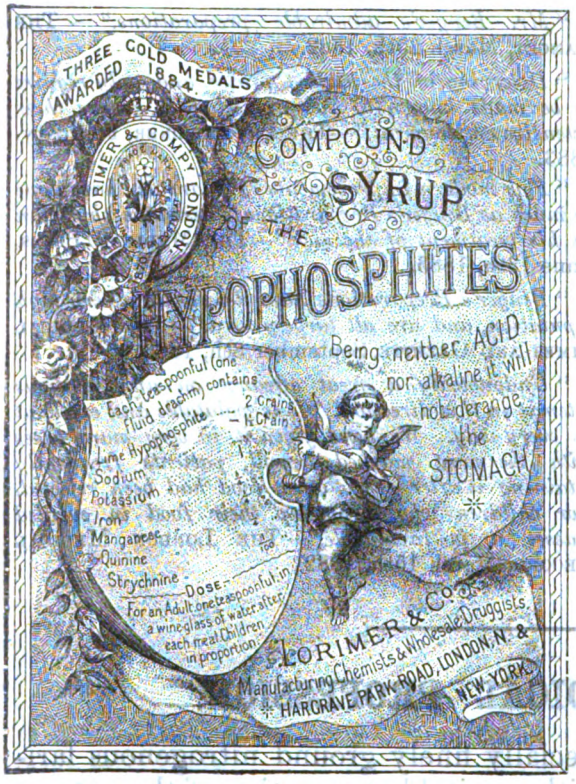
NOTICE TO THE MEDICAL PROFESSION.

BENGER'S FOOD consists of a specially finely ground nitrogenous farinaceous meal, cooked, and impregnated with a suitable proportion of the natural digestive principles of the pancreas. When mixed with warm milk or milk and water, as directed on each tin, these digestive principles not only render the starchy matter soluble (as in malted foods), but further, reduce the casein of the milk to the same flocculent, digestible condition in which it exists in human milk, so that hard indigestible masses of curd cannot be formed in the stomach. In no other Food has this result been attained. It forms a delicate cream entirely free from rough and irritating particles, but rich in all the elements necessary to maintain vigorous health.

SURGEON BARNES, M.S., Sandown, Isle of Wight, writes, under date June 6th, 1886:—

"*Since I have used it the very best results have followed, and after a lengthened experience of Foods, both at home and in India, I consider Benger's Food incomparably superior to any I have ever prescribed.*"

BENGER'S FOOD may be obtained in tins at 1s. 6d., 2s. 6d., and 5s. each of Chemists, &c., everywhere, or by Parcels Post direct from the Manufacturers—



MOTTERSHEAD & CO. (S. PAINE & F. B. BENGER), Pharmaceutical Chemists,

SYRUP HYPOPHOSPH. CO. (LORIMER'S)

ABOVE IS FAC-SIMILE OF LABEL.

In prescribing please write "Syr. Hypophosph. Co. (Lorimer)."

IMPORTANT EVIDENCE.

The originals of these and many other similar Letters may be seen at our Offices.

"Messrs. Lorimer & Co.

"DEAR SIRS,—Your Syrup of Hypophosphites has proved of such *inestimable value* in my own case that I can hardly say too much in its favour as a remedial agent. For five weeks I laboured under great nervous prostration, and was in a semi-anæmic condition, with debility of the digestive organs, and such torpor of the bowels as necessitated the constant use of aperient medicine (a very unusual want with me), which I, aided by the infusions of columba, gentian, &c., accompanied by preparations of iron, with very little benefit, till I happened to see the formula of your Syrup looking over the "British Medical Journal." The action of your preparation has been *all but magical*; by the time I had taken five doses, the obstinate constipation was relieved, my appetite returned, and I felt stronger than I had done for many months previously. I am happy to say these good results have proved to be permanent. "Yours faithfully,

"Birmingham, June 30th, 1886. "A PHYSICIAN."

"Dewsbury, April 25th, 1886.

"An invaluable remedy in Pulmonary Tuberculosis—the patients like it, finding it an agreeable stimulant and tonic, and quickly improving the appetite. I shall in future use it more extensively. "M.D."

"Kirkburton, Yorkshire, March 23rd, 1886.

"Your Syrup of Hypophosphites is an elegant preparation, which is something, and a very effective one, which is everything. I have used it in a number of cases with much success, and shall use no other in future. "M.D."

"Kidderminster, March 23rd, 1886.

"Lorimer's Hypophosphites.—I have given your Syrup Hypophosph. Co. in several cases, and always with marked benefit. I consider it an elegant compound, and superior to all others,

"Honorary Surgeon, Kidderminster Infirmary."

"Clifton, July 20th, 1886.

"I prefer it to any other. It appears to meet the desideratum long sought for—viz., an elegant preparation, definite and stated formula, and moderate price. "M.D."

Has the following advantages over all other similar preparations:—

1st.—It is **not a quack** preparation or secret nostrum, the formula being stated on every label.

2nd.—The **formula is original**, and based on sound scientific theory, borne out by practice. **There is no other preparation** of the Hypophosphites which contains the same proportion, **or so large proportions** (about 6 grains per fluid drachm) of the various salts.

3rd.—It carries all its constituents in **perfect solution**, the last dose being identical with the first. It offers no danger by precipitation of strychnia, as is the case with preparations that require shaking to distribute the dose.

4th.—The formula being stated on every label, **the Physician** is enabled to vary the dose, according to the individual requirements and idiosyncrasies of each patient.

5th.—It is pleasant to take.

6th.—It is **neutral**, or very **slightly alkaline**, and can be taken by persons suffering from the most sensitive stomach, without producing the slightest derangement thereof.

7th.—The price is not a fancy one, 1 lb. bottles, unstamped, for dispensing, **4s.** each; stamped bottles, **24s.** and **42s.** per dozen.

8th.—It may also be had "sine Strychnia."

9th.—It may be diluted with an equal volume of Syrupus P.B.

The product will contain about three grains Hypophosphites per fluid drachm, be most pleasant for children, and **equal in themical and therapeutical value** to either of the **foreign nostrums**, so largely advertised.

10th.—There is not another preparation of a **similar name** which is not either **strongly acid**, or of **unknown composition** (generally varying from ½ to 2½ grain Hypophosphites per fluid drachm), or **deposits its active ingredients**, and many have all these faults.

LORIMER'S SYRUP HYPOPHOSPH. CO. is therefore superior to all others, and free trial samples are supplied to all members of the Medical Profession, in order to enable them to judge of the fairness of this claim.

SPECIAL NOTICE.

"With reference to the foreign manufacturer who claimed to be the inventor of Syrup Hypophosph. Comp., and declared all similar preparations inferior to, and imitations of his own, we have already publicly challenged him to prove either statement, and offered a sum of £200 for London Hospitals if he could succeed. This offer is still open, and we are prepared at any moment to abide by the terms of our challenge."—See THE LANCET, BRITISH MEDICAL JOURNAL, &c.

LIQ. EUONYMIN ET PEPSIN CO.

(OPPENHEIMER'S).

From the BRITISH MEDICAL JOURNAL, Feb. 14th, 1885.

"An exceedingly valuable preparation, combining, in a very useful and palatable form, a valuable hepatic and digestive agent. It meets a want felt by prescribers in the treatment of indigestion and flatulence due to deficient secretion of bile, as well as atony of the stomach and insufficient secretion of gastric juice. . . . In practice we found it very convenient and valuable."

From the EDINBURGH MEDICAL JOURNAL, May 1st, 1886.

"We can confidently recommend it as an excellent preparation in dyspepsia depending on hepatic derangements."

LIQ. EUONYMIN ET CASCARÆ SAGRADÆ CO.

(OPPENHEIMER'S).

This combination of our Euonymin with Cascara Sagrada possesses the following therapeutic action, in addition to the cholagogic action of Euonymin: It stimulates mildly the entire glandular apparatus of the large and small intestines, increasing muscular power and regulating the propelling force, the bowels continuing to act naturally and regularly after the preparation is discontinued, and therefore Liq. Euonymin et Cascaræ Sagradæ Co. will be found most useful in the treatment of CHRONIC CONSTIPATION WITH HEPATIC DERANGEMENTS.

PREPARED ONLY BY

OPPENHEIMER BROS. & CO. (Manufacturing Chemists),

1 & 3, Sun-street, Finsbury-square, London, E.C.

Price 10s. 6d. per pound, packed (for Dispensing only) in 8 oz., 16 oz., 32 oz., and 64 oz. Bottles.

TEST.

One Teaspoonful of
Pepsina Liquida (Schacht)
will Peptonise **1000** grains of Albumen.
A palatable, odourless liquid,
attractive to Patients, and
of guaranteed strength.

SCHACHT'S LIQUID PEPSINE.

We prepare also

PEPSINA LIQUIDA c. BISMUTHO (SCHACHT).

Each drachm contains in a concentrated form, besides the liquid pepsine, a full dose of Schacht's Liquor Bismuthi.

PEPSINA LIQUIDA c. EUONYMIN (SCHACHT).

Each drachm contains one grain of soluble Euonymin.

THE FORMULÆ ARE GIVEN ON EVERY LABEL.

Price of each remedy:—One pound bottles, 7s. each; half-pounds. 3s. 9d.; 4 oz. bottles retail at 2s. 6d.

To be obtained of all the Wholesale Houses; or will be sent direct, post free, or carriage paid, to any address on receipt of remittance by

GILES, SCHACHT, & CO., CLIFTON, BRISTOL.

A NEW THROAT CASE,

REPLETE WITH IMPROVED PRODUCTS.

Voice and Throat.

Of all the diseases which afflict mankind, perhaps none are more prevalent than those of the throat. While in the majority of instances they may not be dangerous, they are none the less annoying to the patient, and relief is none the less earnestly sought. In not a few cases the success with which slight ailments of the throat are treated is the criterion by which patients will form their opinion of a physician's skill. As contributing to the physician's convenience, we have prepared a throat case which may be filled with the following, prepared in the most desirable form.

ZINC "TABLETS."

(1 grain.)

These are most convenient, as the amount required can be dissolved at once without weighing or measuring.

ABSORBENT COTTON.

This will absorb over a dozen times its weight of water. "It is beautifully soft, really absorbent, and quite free from chemicals."—*The Lancet.*

Supplied in packets, 2 oz., 4 oz., and 1 lb. each, to Physicians at 0/8, 1/0, and 3/0.

AMMONIUM CHLORIDE "TABLETS."

"Ammonium chloride considerably increases the secretion from the mucous membrane," and prevents the formation of a thick tenacious mucus. Aside from its value in neuralgia, its usefulness in catarrhal conditions of the throat and lungs is well known. For the throat, it should be dissolved on the middle of the tongue—not near the tip.

Dose.—One to six tablets in plenty of water.

HAZELINE.

"It is useful in ozæna, and, snuffed up the nose, for catarrh" (Ringer's *Therapeutics*). Prescribed for epistaxis.

Price to physicians, 3/6 per lb.; 1/2 per 4 oz. bottle.

EUCALYPTINE.

Eucalyptine is found very efficient in cold in the head, and in nasal catarrh, by simply smelling constantly some cotton on which it has been dropped; even where there is a profuse offensive catarrhal discharge it removes the fœtor and checks the secretion.

PURE TEREBENE (BURROUGHS).

The value of this special preparation in chronic catarrhal affections of the throat and lungs is widely known.

COMPRESSED CHLORATE OF POTASH "TABLETS."

In acute sore throat, Chlorate of Potash "usually relieves the uneasiness in a few hours" (Cohen).

CHLORATE OF POTASH & BORAX "TABLETS."

Prescribed for aphthous ulceration, cracked tongue, hoarseness, clergyman's sore throat, aphonia, and diphtheria. "The Wyeth Tablets are manufactured with the utmost neatness and perfection" (*British Medical Journal*).

VOICE "TABLOIDS."

These contain COCAINE, Chlorate of Potash and Borax, and are highly praised by many.

TRYPSIN (FAIRCHILD).

This has been found very active in digesting off the membrane in diphtheria, by Dr. J. Lewis Smith and others.

PULV. IPECAC "TABLETS" (5 gr).

These are always ready for use; three or more of them may be crushed, and taken in a little water, for croup, etc.

POTASSIUM PERMANGANATE "TABLETS."

"In cases of ozæna it is employed to wash the nose, and as a lotion or gargle to the mouth in ulceration with fœtor, such as mercurial stomatitis, and also in diphtheria" (Brunton).

BISMUTH SUBNITRATE "TABLETS."

One of these may be quickly powdered for purposes of insufflation into the nares.

VALOID FLUID EXTRACT HYDRASTIS.

"*Stomatitis*, both mercurial and aphthous, is much improved by local application of the fluid extract of hydrastis. When this preparation causes much smarting, it may be diluted with water. Follicular pharyngitis, chronic coryza, and even syphilitic affections of the mouth, throat and nares, may be much benefited or even cured by the same application". (Bartholow).

VALOID FLUID EXTRACT ACONITE ROOT.

"In membranous croup," says Phillips, "I have seen decided relief from aconite in the early stages." He strongly recommends it in follicular and simple tonsillitis. Dose.—One-eighth of a drop.

VALOID FLUID EXTRACT BELLADONNA.

"Belladonna may be given with aconite internally in severe inflammatory diseases, especially where the throat and tonsils are acutely inflamed and much swollen" (Ringer).

The Physician's Throat Case is of Flexible Fine Calf, containing 16 3-drachm Vials, Price, fitted 27s. 6d.

BURROUGHS, WELLCOME & CO., Snow Hill Buildings, LONDON, E.C

RICH IN DIASTASE.

Maltine

(REGISTERED.)

RICH IN PHOSPHATES AND ALBUMINOIDS.

At the International Health Exhibition, London, 1884, all the principal Extracts of Malt at present before the Profession were examined by a Jury of the highest scientific attainments, and the Only Gold Medal was awarded to Maltine. We submit that this affords irrefragable proof of the superiority of Maltine (extract of malted wheat, oats, and barley) to the ordinary extract of malt made from barley only.

SCIENTIFIC OPINIONS ON MALTINE.

Prof. ATTFIELD:—"Maltine contains unimpaired, and in a highly concentrated form, the whole of the nutritive materials that it is possible to extract from either malted wheat, malted oats, or malted barley. It contains from *three* to *five* times as much diastase as any other Extract of Malt in the market. Its flavour and odour are those of a delicious sweetmeat."

Prof. TICHBORNE:—"Having examined the principal unfermented Extracts of Malt in the market, I find Maltine is the richest in two of the most important ingredients in these foods—namely, the *phosphates*, or *bone-formers*, and that peculiar farinaceous digestive called diastase. In this combination of barley, wheat, and oats, we get a food which is readily digested for use, a condition of *immense value* to the physician."

Prof. MACADAM, Edinburgh:—"I have carefully analysed Maltine, and contrasted the results with four other well-known Extracts of Malt in all the digestive and nutritive properties; the Maltine *materially exceeds* in power and efficacy any of the others."

Prof. STUTZER, Bonn:—"The nitrogenous substances which Maltine contains are considerably richer than any other Extract of Malt in the market. As to diastase-converting power, Maltine is *far superior* to the best Extracts of Malt I have ever seen."

Prof. C. MEHU, Paris:—"The Maltine is perfectly prepared and of easy preservation; repeated experiments show that the Maltine converts 25 to 30 times its own weight of starch into sugar."

Prof. DEPAIRE, Brussels:—"One part of Maltine dissolves 27 to 29 parts of starch. It contains more *flesh-forming* and *bone-producing substance* than other Extracts of Malt. This is of immense importance to those who use Extract of Malt."

THE LANCET:—"Maltine exhibits in an eminent degree the starch-dissolving power of diastase; in fact, a single spoonful is capable of converting instantaneously a surprising amount of stiff starch paste into a thin limpid liquid."

Prof. L. P. YANDELL:—"In convalescence it is a delightful and efficacious cordial. We have invariably found it liked by children."

SAVORY & MOORE'S SPECIALITIES.

Gold Medal, Health Exhibition, 1884. Gold Medal, Liverpool Exhibition, 1886.

The Best Food for Infants.

Used in the Royal Nurseries.

Tins, 1s., 2s., 5s., 10s.

A Self-Digesting Food, supplying the highest amount of bone and flesh-forming constituents.

"This is an admirable preparation, and I am confident that to it many infants owe their lives."—See GLASGOW MEDICAL JOURNAL, May, 1885.

"The constant employment by medical men of Savory & Moore's Malted Food in rearing their own families is itself a sufficient indication of the estimation in which it is held by those who can best judge of its merits."—MEDICAL PRESS, &c., August 13th, 1886.

"A great improvement on the ordinary kinds."—THE LANCET.

"It can be taken when nothing else can."—MEDICAL PRESS.

Pancreatic Emulsion.

The Essential Form of Nutriment in all Cases of Consumption, Wasting, Loss of Appetite, Strength, and Digestive Power.

In Bottles, 2s. 6d., 4s. 6d., 8s.

Pancreatine Essence.
Pepsine Essence.

"Savory's Essences are preferable to other liquid preparations."—BRITISH MEDICAL JOURNAL.

Bottles, 2s. 6d., 4s. 6d., 8s. 6d.

Pancreatine Wine.
Pepsine Wine.

Bottles, 3s., 5s., 10s.

Datura Tatula for Asthma.

Cigars and Cigarettes—Boxes, 3s., 6s., 8s., 15s.
Tobacco—Tins, 2s. 6d., 5s., 10s., 18s.
Pastilles and Powder (for Non-Smokers' use)—Boxes, 2s. 6d., 5s., 10s.

Dr. Jenner's Absorbent Lozenges,

For Acidity and Indigestion.

Speedily and effectually correct Heartburn, Flatulence, and other evils attendant on a superabundance of acid in the stomach.

They are eminently serviceable in relieving that form of HEARTBURN *so common with ladies during pregnancy.*

Boxes, 1s. 1½d., 2s. 9d., and 10s. 6d.

Meat Peptone.

In Jars, 3s., 5s. 6d., and 10s.

"The objection commonly made to all preparations of Meat Peptones is that they have a nauseous, sickly taste. The difficulty has at last been overcome by Messrs. Savory & Moore, who have recently introduced a Meat Peptone which fulfils all the requirements of the sick room."—THE LANCET, June 5th, 1886.

"Messrs. Savory & Moore's Meat Peptone is an admirable preparation for invalids. When the teeth are decayed, or the digestion is impaired, it may be spread on bread-and-butter, or eaten in the form of a sandwich. In cases of great exhaustion it is valuable as a restorative agent. We can cordially recommend it."—BRITISH MEDICAL JOURNAL, March 13th, 1886.

Pure Peptone.

In Bottles, 3s. 6d.

Peptic Salt.

A very convenient and efficacious digestive agent, to be taken freely at meals, in the same way as ordinary Salt.

Bottles, 2s. 6d., 7s. 6d.

Peptonising Pellets.

"The peptonising Pellets are excellent, and will be found useful for predigesting milk."—THE LANCET, June 5th, 1886.

"They are very active, and do not require a large excess of alkali, which we consider a feature of much importance, especially in infant feeding. The milk peptonised by the pellets is of very fine flavour."—BRITISH MEDICAL JOURNAL, April 3rd, 1886.

Bottles, 2s. 6d.

Peptone Lozenges.
Peptone and Coca Lozenges.

Afford an excellent and convenient concentrated sustenance.

In Boxes at 2s. 6d.

Coca Wine.

Possesses in an eminent degree the valuable tonic and invigorating properties of Erythroxylon Coca, the celebrated Peruvian restorative.

Bottles, 4s. 6d.

J. F. MACFARLAN & CO.,

MANUFACTURERS OF

ANTISEPTIC DRESSINGS AND APPLIANCES USED IN THE LISTERIAN SYSTEM OF SURGERY.

Our Listerian Dressings were the first in the Market, and were prepared under the guidance of Professor Sir Joseph Lister and according to his private Formulæ, which have since been published. These Dressings are now known and used wherever the Antiseptic Method is employed in Surgical Practice. The demand which followed their introduction, and which has since continued steadily to increase, warrants us in believing that the accuracy with which, for the last fifteen years, they have been prepared has secured the confidence of the Profession.

PRICE LISTS ON APPLICATION.

Edinburgh address—17, NORTH BRIDGE. London address—71, COLEMAN ST., E.C.

Telegram address—"Morphia," Edinburgh or London.

OBSTETRIC CONES (GALE'S).

Cocaine, Boric Acid, and Cocao Butter.

Specially recommended by Mr. E. HEAD MOORE, L.R.C.S., &c., in primiparæ and cases of rigid os.

These Cones are made hollow, and of a size that will fit the index finger; they possess great advantages over the existing methods of applying Cocaine to the os uteri, &c. They can be introduced without the patient's knowledge, and Cocaine in this form is applied without the use of a speculum and the consequent exposure of the patient, whilst the Cocao Butter acts as a lubricator to the parts.

May be obtained, containing 1, 2, or 3 grains of Cocaine in each Cone, in boxes of 12 and 6.

MANUFACTURED ONLY BY

GALE & COMPY., 15, Bouverie-street, Fleet-street, London. E.C.

Vaginal Pessaries of all kinds made on the hollow principle, if required.

FERRIS & CO.'S

ANODYNE AMYL COLLOID.

(Registered under the Trade Marks Act.)

Messrs. FERRIS & COMPANY beg to direct attention to the following important and unsolicited Testimonial recently received from Dr. RICHARD LOWTHER, Fernleigh, Grange-over-Sands.

Sept. 26th, 1886.

DEAR SIRS,—It will be a satisfaction to you to learn that in a case of most severe intercostal neuralgia, complicating an attack of shingles, which was rapidly exhausting an aged patient of mine, instant relief resulted from the first application of your Anodyne Amyl Colloid, after numerous other remedies had been tried without benefit. I have found it also the best of all remedies in chilblains. I shall be glad if its beneficial effects become more generally known.

Yours faithfully, RICHD. LOWTHER, M.D.

In bottles stamped, 2s. 9d., 4s. 6d., 8s., and 15s. each.; price to Surgeons, 2s., 3s. 6d., 6s. 6d., and 12s. 6d. each. Bottles and stamps included.

IMPORTANT CAUTION.—Medical Gentlemen are earnestly and respectfully desired to observe that they are supplied with FERRIS & CO.'S ANODYNE AMYL COLLOID. This preparation differs essentially from all others. Some UNRELIABLE and USELESS imitations are being advertised, which bear no resemblance either in composition or effect to Ferris & Co.'s special formula. See that every bottle bears FERRIS & CO.'S Registered Trade Mark.

Tasteless. Pure. Active.

Sold everywhere at 6d., 1/, 1/9 & 3/.

PRIZE OF 16,600 FRANCS DE L'INSTITUT DE FRANCE.

QUINA-LAROCHE

LAROCHE'S TRIPLE QUININE WINE.

This ELIXIR is the most powerful and valuable of the preparations of Quinine as a strengthening and anti-febrile restorative. It has a very pleasant taste, and has been employed in the hospitals with immense success in cases of Weakness and General Debility, Loss of Appetite, Indigestion, Changes of Life, Nervousness, Exhaustion, Slow Convalescence, Fevers, and the After Effects of Fevers which have resisted all Quinine.

ALSO prepared with IRON—
For Purifying the Blood,
For Scrofulous Affections,
For Chlorosis.

Paris: 22, rue Drouot. London: Newbery & Sons.

INTERNATIONAL and UNIVERSAL EXHIBITION, LONDON, 1884—FIRST-CLASS CERTIFICATE and GOLD MEDAL; and CALCUTTA EXHIBITION—FIRST-CLASS CERTIFICATE and SILVER MEDAL for the superiority of our Pharmaceutical Preparations.

PURE TEREBENE (Hewlett's).

PURE TEREBENE is strongly recommended in "Winter Cough," Chronic Bronchitis, Emphysema, Phthisis, Bronchorrh, &c.; in those cases aggravated with a dyspeptic element, it controls the complication at once. Dr. MURRELL says: "It checks the formation of flatus so quickly, and is so efficacious in expelling any that may remain in the stomach or intestines, that I constantly employ it in cases of Dyspepsia when flatulence is a prominent symptom. Patients like it, and often continue taking it for months or years. It acts as an antiseptic, probably much in the same way as glycerine, oil of cajeput, and oil of eucalyptus. I am surprised that it has not come more largely into use in the treatment of flatulence. Pure Terebene is of such value in winter cough that I rarely experience the necessity of resorting to other remedies. It is a powerful expectorant, and if inhaled the first thing in the morning, when the mucous membranes are covered with thick viscid secretion, will give very great relief. Pure Terebene is a valuable remedy, and will in time come largely into use."—Vide BRITISH MEDICAL JOURNAL, Dec. 12th, 1885, page 1103.

TEREBENE (Hewlett's) is pleasant to take, and has the agreeable odour of fresh sawn pine. The dose is ten drops on a piece of sugar three or four times a day. It is so effective that its remedial value is apparent in a day or two.

We would warn the Medical Profession against the common Terebenes placed on the market, which, owing to the impurities they contain, do the patient harm. We guarantee our Terebene to be pure, having the most delicate fragrance of pine—a proof of its purity. We invite comparison by the Medical Profession and Pharmaceutical Chemists.

Packed in 5-oz., 10-oz., 22-oz., 40-oz., and 90-oz. bottles. Physicians will oblige by writing "Terebene Pure (Hewlett's)."

Prepared by C. J. HEWLETT & SON, 40, 41, and 42, Charlotte-street, London, E.C.

WRIGHT'S LIQUOR CARBONIS DETERGENS.

See Recommendatory Notices of Medical Press and Opinions of the leading Dermatologists

Extract from the Proceedings of the Royal Society, Edinburgh.

"Experiments on the Chief Disinfectants of Commerce with a view of ascertaining their Power of Destroying the Spores of the Anthrax Bacillus, by a Medical Officer of Health and Public Analyst.

"LIQUOR CARBONIS DETERGENS.—This is a solution of certain coal-tar products in spirit. It forms with water an emulsion. Added to water in the proportion of 5 per cent., it had but feeble influence in preventing the subsequent growth of anthrax. A 10 per cent. solution, acting for four hours, distinctly retarded growth, for the spores, whether on gelatin-pork or in the broth, did not commence developing for twenty-four hours. Undiluted Liquor Carbonis Detergens, acting for four hours arrested future growth."

THE PRACTITIONER of September, 1881:—"Itching, which owes its origin to too slow a current of blood, of which the most typical example is that seen in Eczema connected with varicose veins of the leg—also Pruritus Scroti, Labiorum and Ani—is best relieved by weak tarry lotions, one of the best of which is Wright's Liquor Carbonis Detergens; a well-made alcoholic solution of coal tar suitably diluted."

From THE LANCET, Dec. 22nd, 1866:—"In our hands it has been a most effective agent in skin diseases, especially of the chronic eczematous class; and one case of psoriasis, which had resisted all other kinds of treatment, speedily got well under the application of the Liquor Carbonis Detergens. We esteem it a very valuable addition to our list of skin remedies."

From the MEDICAL TIMES AND GAZETTE, January 19th, 1867:—"We have more than once called attention to the value of this remedy in chronic eczema."

From the BRITISH MEDICAL JOURNAL, September 22nd, 1871:—"We have tested it, and can affirm its value as a detergent agent. We consider the Liquor is an article of great utility."

CARBONIS DETERGENS.

Kept in stock and sold by all Druggists (Wholesale and Retail) throughout the United Kingdom and Colonies.

Proprietors: W. V. WRIGHT & CO., Southwark, London, S.E.

THE PERFECTION OF CLEANLINESS, UTILITY, AND SIMPLICITY.

TWYFORD'S "UNITAS,"

Combining W.C. BASIN and TRAP, URINAL and SLOP SINK, has the following Special Advantages:—

Unlike ordinary W.C. Basins, *it is not enclosed with woodwork*, but is fully exposed, so that no filth, nor anything causing offensive smells can accumulate, or escape detection.

All joints and connexions *being in sight*, any leakage or other defect can be easily detected and remedied.

No Wood Fittings are required except a hinged seat, which being raised, the Basin can be used as a Urinal or a Slop Sink, the "wetting" so objectionable in Closets having permanent seats being avoided. Free access can thus be had to all parts of the Basin and Trap, so that everything about the Closet can be easily kept clean.

Made with or without Slop Top in three ways.

No. 1. With raised Ornamentation, Oak or Florentine Pattern (White or Ivory).
No. 2. Plain, White or Ivory, or with Printed Pattern.
No. 3. In strong Fire Clay, specially adapted for Factories, Workhouses, Asylums, Infirmaries, Hospitals, &c. &c.

The flushing arrangements are so perfect, that with a flush of two gallons of water, it is guaranteed that all the soil and paper will be completely removed from the Basin, and through the Trap, the whole of the inside being thoroughly washed, and with the aid of the Patent "After-flush" Chamber, the full quantity of water required to receive the soil is left in the bottom of the Basin.

THOMAS W. TWYFORD,
Manufacturer of all Descriptions of Sanitary and Plumbers Earthenware, and Sole Maker of the "Unitas," "National," "Alliance," and "Crown" Closet Basins.
Hanley, Staffordshire.

St. Bartholomew's Hospital and COLLEGE.

The SUMMER SESSION begins on Monday, May 2nd.

The Hospital comprises a service of 750 beds (including 75 for convalescents, at Swanley).

Students may reside in the College within the Hospital walls, subject to the collegiate regulations.

For particulars, apply personally, or by letter, to the Warden of the College, St. Bartholomew's Hospital, E.C. A handbook forwarded on application.

St. Bartholomew's Hospital and COLLEGE.

OPEN SCHOLARSHIPS IN SCIENCE.

Two Scholarships of the value of £130 each, tenable for one year, will be competed for on September 27th and three succeeding days. One of the value of £130 will be awarded to the best candidate at this Examination under twenty years of age, if of sufficient merit. For the other, the candidates must be under twenty-five years of age.

The subjects of examination are Physics, Chemistry, Botany, Zoology and Physiology. No candidate to take more than four subjects.

The Jeaffreson Exhibition will be competed for at the same time. The subjects of Examination are Latin, Mathematics, and any two of the three following languages: Greek, French, and German. This is an open Exhibition of the value of £50.

Candidates must not have entered to the Medical or Surgical Practice of any Metropolitan Medical School.

The successful candidates will be required to enter at St. Bartholomew's Hospital in the October succeeding the Examination, and are eligible for the other Hospital Scholarships.

For particulars, application may be made to the Warden of the College, at St. Bartholomew's Hospital, E.C.

The Royal Westminster Ophthalmic HOSPITAL, King William-street, Charing-cross.

The Practice of this Hospital is open to Practitioners and Students from 1 to 4 P.M. daily.

Special Instruction is given in the Diagnosis, Pathology, and Treatment of all EYE AFFECTIONS, including the Operations on the Eye, the Treatment of Errors of Refraction, and the use of the Ophthalmoscope.

The next Clinical Evening, Friday, May 6th, at 8 P.M.: Mr. ROUSE and Mr. HARTRIDGE.

Terms for six months, £3 3s. Perpetual, £5 5s.

For particulars apply to Mr. Juler, 77, Wimpole-street, W.

Westminster Hospital Medical School,

Caxton-street, S.W.—The SUMMER SESSION commences on May 1st. A Science Scholarship, value £40, is offered for competition. The examination will be in Chemistry (Organic and Inorganic) and Physics, and will be held on April 30th. In September Entrance Scholarships, value £80 and £40, will be offered for competition.

Students entering in the summer (except those who have already obtained a Scholarship) are allowed to compete for the Entrance Exhibitions in the following September.

Fees: £100 in one sum on entrance, or 100 guineas in two payments, or £115 in five payments. No extras, except parts for Dissection and Class of Experimental Physics.

For prospectus and particulars apply to

F. DE HAVILLAND HALL, M.D., Dean.

Charing-cross Hospital Medical SCHOOL.

SUMMER SESSION, 1887.

Lectures and Clinical Instruction in the Wards will commence on Monday, May 2nd, at 9 A.M.

Gentlemen can enter to any Course of Lectures, or to Hospital Practice only.

The Hospital has a service of 230 beds for Clinical Teaching, including those of the adjoining Royal Westminster Ophthalmic Hospital, to which General Students are free.

Two ENTRANCE SCHOLARSHIPS of £30 and £20 respectively, for which General Students now entering can compete, are awarded annually in October.

The LLEWELLYN SCHOLARSHIP of £35 and the GOLDING SCHOLARSHIP of £15 are open to General Students who have completed their third and first academical years respectively.

The PEREIRA PRIZE of £5 is open to all General Students, and is awarded for the best Clinical Reports.

Students are eligible for the appointments of Resident Medical, Surgical, and Obstetrical Officer, for Clinical Clerkships, Surgical Dresserships, and for Assistant Demonstratorships of Anatomy, Physiology, &c., without additional fee.

FEES.—For the curriculum of Study required by the various examining bodies and hospital practice, 90 guineas in one sum, or 100 guineas in five instalments. The Composition fee for Dental Students is £42 2s., payable in two instalments.

*** The hours of Lectures have been specially rearranged to suit the convenience of Dental Students. Charing-cross Hospital is within three minutes' walk of the Dental Hospital of London.

PRELIMINARY SCIENCE INSTRUCTION.—Arrangements have been made for Students desirous of undergoing a Course of Instruction in Science, such as that required for the Preliminary Scientific (M.B.) Examination of the University of London, to attend at the Normal School of Science, South Kensington.

A Prospectus containing every information will be forwarded on application to the Librarian and Secretary, Mr. J. Francis Pink, who attends daily at the Office of the School, Chandos-street, Charing-cross, between the hours of 10 and 4.

J. MITCHELL BRUCE, M.A., M.D., Dean.

St. George's Hospital Medical School, HYDE-PARK-CORNER, S.W.

The SUMMER SESSION will commence on Monday, May 2nd.

The Fees for Perpetual Students are £125 on entrance, or £130 paid by instalments extending over three years.

£10 10s. will be deducted from these fees in the case of Students who, under the Conjoint Scheme, do not require instruction in Chemistry and Materia Medica.

Second and third-year Students are received upon payment of £90 and £85 respectively.

Dresserships, Clerkships, and all the House Appointments are awarded without extra fees, and the latter on the result of competition.

The William Brown £100 Exhibition, tenable for two years, and the £40 Exhibition, tenable for three years, are open to all Perpetual Students.

The following Entrance Scholarships are offered for competition in October, and Students entering in the Summer Session are eligible to compete for them:—

1. A Scholarship, value £125, for the Sons of Medical Men who have entered the School during the current year.

2. Two Scholarships, value £50 each, open to all students commencing their studies in May or October. Subjects: Latin, French or German, and Elementary Physics.

3. A Scholarship, value £90, open to all students who have entered the School during the current year, having passed the Cambridge 1st M.B. since the previous October. Subjects: Practical Chemistry and Elementary Biology, Physiology and Anatomy.

4. A Scholarship, value £65, open to all students who have entered the school during the current year, having been previously signed up for or passed the Oxford 1st M.B. or Cambridge 2nd M.B. Subjects: Anatomy and Physiology.

Other Prizes of the value of £150 are offered for competition annually.

The Appointments of Obstetric Assistant, with a salary of £100 a year and board and lodging; Curator, £50; Medical and Surgical Registrars, £50 each, are awarded yearly upon the recommendation of the Medical School Committee.

The New Physiological Laboratories are now finished, and have been placed under the superintendence of Dr. Delépine.

Prospectuses and further details may be obtained by application to

WILLIAM WADHAM, M.D., Dean.

St. Mary's Hospital Medical School.—

The SUMMER SESSION will commence on May 2nd. The Hospital contains 281 beds, is situated in one of the most pleasant districts of London, and is in direct communication by rail with all parts of the Metropolis. Several Scholarships in Natural Science will be offered for competition in September. Students entering in May are eligible to compete for these Scholarships. Special classes are held for the Preliminary Scientific Examination of the University of London. Fee £10 10s., which will be returned to any member of the class who enters as a Perpetual Pupil. Gentlemen who enter for this course count their medical studies from the time at which they commence their attendance on the Lectures on Anatomy and Physiology.

The School buildings, to which large additions were made in 1883, especially as regards the laboratories for the teaching of Physiology and Chemistry, have been further enlarged this year by the addition of a wing containing a new Library, Pathological Laboratory with arrangements for Bacteriological research, and various class-rooms for Anatomy, Physiology, and Chemistry. In the Students' Club a larger Dining Hall and Reading Room have been added.

The course of teaching at this School insures careful and complete preparation for all the Examining Boards, the Public Services, and the higher University examinations.

In addition to the clinical instruction and lectures given in the wards daily, distinct Clinical Lectures will be given on Fridays throughout the academical year at 4 P.M.

The medical, surgical, and obstetric tutors assist the students in preparing for the final examinations.

Post-Graduate Course.—These lectures and demonstrations are given on Saturdays, at 4 P.M.

All the Medical Appointments in Hospital, including the seven House-Surgeoncies, are open to pupils without additional fee or expense of any kind.

For prospectus and further information, apply personally at 4 P.M. or by letter to

GEORGE P. FIELD, Dean.
SIDNEY PHILLIPS, M.D., Sub-Dean.

RESIDENCE FOR STUDENTS.

St. Mary's Hospital Medical College,

33 and 35, Westbourne-terrace, W.

Students may reside in the College under the supervision of the Warden, Dr. Robert Maguire.

Terms, 90 guineas for the academical year, payable 30 guineas in advance on Oct. 1, Jan. 1, and May 1, to include special instruction by the demonstrators on four days a week. The Warden will be happy to show the arrangements of the College, or to give any further information concerning it.

Curriculum of the M.D. Degree,

LONDON.—Students who have matriculated and are intending to enter, or who have already entered, at any one of the London Medical Schools for the purely Medical portion of their studies can prepare for the PRELIMINARY SCIENTIFIC EXAMINATION at University College, under Professor Williamson, LL.D., F.R.S., Professor Carey Foster, F.R.S., Professor Oliver, F.R.S., and Professor Lankester, LL.D., F.R.S.

Fee for the complete course of study required, including lectures and laboratory work, 35 guineas.

For particulars, apply to the Secretary, University College, Gower-street.

Digitized by Google

POST GRADUATE COURSE.

St. Mary's Hospital Medical School.

The following Lectures and Demonstrations will be given by Mr. MALCOLM MORRIS, on Saturdays, at 4 P.M.

Practical Demonstrations.

April 23rd—Eczema.
" 30th—Psoriasis.
May 7th—Tinea Tonsurans.
" 14th—Lupus Vulgaris.

Cases will be shown, and new methods of treatment explained.

Fee £1 1s. for the course.

For further information apply to

GEORGE P. FIELD, Dean.
SIDNEY PHILLIPS, M.D., Sub-Dean.

Royal London Ophthalmic Hospital,

Moorfields, E.C.

Two months' course of practical instruction.

Use of the Ophthalmoscope every Monday and Thursday at 7.30 P.M., commencing on Monday, May 9th, by Messrs. Gunn and Silcock. Fee £2 2s.

Refraction of the Eye every Tuesday and Friday at 7.30 P.M., commencing on Tuesday, May 10th, by Mr. Lang. Fee £2 2s.

A few Clinical Lectures will be delivered by Mr. Nettleship during the course. Notice of these will be given at the Hospital.

ROBERT J. NEWSTEAD, Secretary.

University College, London.—Faculty

OF MEDICINE.—The Summer Session will begin on May 2nd. Prospectus containing full information respecting the Classes in the College, Clinical Instruction at the Hospital, Scholarships, Exhibitions, &c., may be obtained at the offices of the College, Gower-street, W.C.

G. V. POORE, M.D., Dean of the Faculty.
J. M. HORSBURGH, M.A., Secretary.

University College, London. — Ad-

VANCED INORGANIC CHEMISTRY.—Dr. S. Rideal will give a course of Thirty Lectures, on Mondays, Wednesdays, and Fridays, at 4 P.M., commencing April 20th. The course is fitted for students reading for honours in chemistry at the University of London July Examinations. Recent progress in physical chemistry and the study of the rarer elements form part of the course. Fee £2 2s.

J. M. HORSBURGH, M.A., Secretary.

St. Thomas's Hospital Medical School,

Albert Embankment, S.E.

The SUMMER SESSION will commence on May 2nd. Students entering in the summer are eligible to compete for the Science Scholarships of 125 guineas and £60, awarded in October.

There are numerous prizes and scholarships, and all appointments are open to students without extra charge.

Special Classes for the Examinations of the University of London are held throughout the year. A register of approved lodgings and of private families receiving students to reside is kept in the Secretary's Office.

Prospectus and all particulars can be obtained from the Medical Secretary, Mr. G. Rendle.

W. M. ORD, Dean.

Guy's Hospital Medical School.—The

SUMMER SESSION commences on Monday, May 2nd. The Hospital contains, besides the beds for medical and surgical cases, wards for obstetric, ophthalmic, and other special departments. Special classes are held in the hospital for students preparing for the examination of the University of London and other examining boards. Appointments: The House-Surgeons and House-Physicians, the Obstetric Residents, Clinical Assistants and Dressers, are selected from the students according to merit, and without payment. There are also a large number of junior appointments, every part of the hospital practice being systematically employed for instruction. Entrance Scholarships: Open Scholarship of 125 guineas in Classics, Mathematics, and Modern Languages. Open Scholarship of 125 guineas in Chemistry, Physics, Botany, and Zoology. Students entering in May are eligible for the Open Scholarships competed for in September. Seventeen Scholarships, Prizes, and Medals, varying from £50 to £10 each, are open for competition to all the students. The Hospital is in close proximity to the Metropolitan, District, South-Eastern, Brighton, Chatham, North London, and Great Eastern Railway Systems.

For Prospectus, apply to the Dean, Dr. F. Taylor, Guy's Hospital, London, S.E.

March, 1887.

London Hospital and Medical College,

Mile-end, E.—The SUMMER SESSION will commence on Monday, May 2.

The New College Buildings are now complete, and afford more than double the former accommodation.

Intending Students are advised that, under the New Regulations of the Examining Board in England, it is exceedingly advantageous to enter for the Summer Session. Students now entering are also eligible for the Entrance Scholarships in September.

The Hospital contains nearly 800 beds, and is the largest General Hospital in Great Britain.

General Fee for Lectures and Hospital Practice 90 guineas in one sum, or 100 guineas in three instalments. The Resident and other Hospital Appointments are free to full Students.

Special entries may be made for Medical and Surgical Practice, also for the Course of Practical Surgery.

The London Hospital is now in direct communication by rail and tram with all parts of the Metropolis, and the Metropolitan, Metropolitan District, South-Eastern, and East London Railways have stations within a minute's walk of the Hospital and College.

For Prospectus and particulars apply to

MUNRO SCOTT, Warden.

The Throat Hospital, Golden-square, W.

CLINICAL EVENINGS.

Cases of interest will be exhibited by Members of the Staff on the following date, at 8.15 P.M.:—

Wednesday, April 27th.

Limelight illumination will be used. Medical practitioners and senior students will be admitted.

T. MARK HOVELL, Dean.

King's College, London.

SUMMER SESSION.—The Lectures will commence on Monday, May 2nd.

Botany—Professor Robert Bentley, F.L.S.
Materia Medica and Therapeutics—Professor Tirard, M.D.
Obstetric Medicine—Professor W. Playfair, M.D.
Forensic Medicine—Professor Ferrier, M.D., F.R.S.
Practical Chemistry—Professor C. L. Bloxam, F.C.S.
Demonstrators—J. M. Thomsen, F.C.S., and G. S. Johnson, F.C.S.
Practical Physiology—Professor Gerald F. Yeo, M.D.
Demonstrators—E. M. Crookshank, M.B., and E. H. Herroun.
Pathological Anatomy—Professor A. B. Duffin, M.D.
Osteology—Professor Curnow, M.D., and A. S. Kenny.
Clinical Therapeutics—Professor Burney Yeo, M.D.
Dean—Professor Curnow.

All intending students who have passed a Preliminary Examination in Arts are informed that under the new regulations of the Royal College of Physicians it is advisable to begin their studies in the Summer Session.

PRELIMINARY SCIENTIFIC EXAMINATION OF THE UNIVERSITY OF LONDON.

The Course of Lectures, Special Classes, and Demonstrations of Practical Chemistry, Botany, Practical Biology, and Experimental Physics for this Examination will commence on Saturday, April 30th, and will be continued during the months of May, June, and July. There are also Special Classes and Special Tutors for all the Medical Examinations, without extra fees.

KING'S COLLEGE HOSPITAL.

Clinical Lectures are given daily by the Physicians and Surgeons.

Clinical Instruction is also given in Diseases of the Eye and Throat, in Skin Diseases, and in Diseases of the Ear.

Ophthalmic, Dental, Aural, Skin, and Throat Departments, and a Ward for Children are attached to the Hospital.

The Physician's Assistant, Physician-Accoucheur's Assistant, and House-Surgeons, as also their Assistants, Ophthalmic Clinical Assistants, Clinical Clerks, and Dressers, are selected by examination from amongst the Students, without extra fees; and those who are elected to the Resident Appointments at the Hospital have rooms and commons free.

SCHOLARSHIPS, REGISTRARSHIPS, AND PRIZES.

WARNEFORD SCHOLARSHIPS.—Students entering the Medical Department of this College at this time will be eligible to compete in October for Two Scholarships of £25 per annum each, to be held for three years. These Scholarships are given for proficiency in Divinity, Classics, Mathematics, History, and English.

Five Medical Scholarships are awarded at the close of each Winter Session for proficiency in professional subjects—viz., one of £40 for two years, one of £30 for one year, and three of £30 for one year.

A Resident Warneford Scholarship of £25, for two years, is also annually awarded for proficiency in Divinity, Medicine, Surgery, and Hospital Practice.

Sambrooke Registrarships: Two of £50, tenable for two years, are annually awarded to Matriculated Students of this department.

Daniell Scholarship: One of £20, for two years, given for proficiency in Chemistry.

Science Scholarships: One annually of £50, for two years, and one of £25 for two years, given by the Clothworkers' Company.

Sambrooke Exhibitions: Two annually, one of £60 and one of £40, for proficiency in Science.

Rabbeth Exhibition: One annually of £30 for the subjects of the Preliminary Scientific M.B. London.

Endowed Prizes of the value of £35, £15, £10, and £4 4s. each, and College Prizes of the value of £60, are annually awarded.

For prospectuses apply, personally or by post-card, to J. W. Cunningham, Esq., Secretary, from whom or from Professor Curnow, Dean of the Department, further information may be obtained.

SCHOOL OF

ANATOMY, PHYSIOLOGY, SURGERY,

and all PROFESSIONAL SUBJECTS: Practically taught by different masters. DISSECTING-ROOM, PHYSIOLOGICAL, CHEMICAL, and PHARMACEUTICAL LABORATORIES. Prospectus on application to Mr. THOMAS COOKE, F.R.C.S., Senior Assistant-Surgeon to the Westminster Hospital, who conducts the Classes of Anatomy and Surgery. Private address—40, Brunswick-square, W.C. Special tuition of an evening for resident pupils.

Chemistry, Materia Medica, Pharmacy, Operative Surgery, Fellowship of R.C.S., H.M.'s Services.

Special Classes for above.

By decision of the Royal Colleges of Physicians and Surgeons gentlemen reported at their Anatomical and Physiological Examinations (Primary, R.C.S. or Second Conjoint) except "signed up" from this School.

Mr. Cooke's Tablets of Anatomy,

price 7s. 6d. (Longmans), contain "in the fewest words and plainest language, and in about one-tenth the space, the matter which is found in the most accredited standard works."—THE LANCET.

Society of Apothecaries of London.—

The next Examination in Arts will be held at their Hall, Blackfriars, E.C., on Friday and Saturday, the 3rd and 4th of June, 1887.

This examination will qualify candidates for registration as Medical Students.

A Syllabus of the subjects, which, according to the regulations of the General Medical Council, may be passed at one or more examinations, can be had on application.

An Examination in Arts will again be held on the 2nd and 3rd of September, 1887.

T. PEREGRINE, M.D., Secretary to the Board of Examiners.

Cambridge Examination in Public

HEALTH.—A Special Class, to include Laboratory Instruction, will be formed in May to prepare for the October examination.—Address, Hygiene, THE LANCET Office, 423, Strand, W.C.

Guy's Hospital Medical School.—

UNIVERSITY OF LONDON PRELIMINARY SCIENTIFIC (M.B.) EXAMINATION.—Instruction is given in all the subjects of the above Examination at GUY'S HOSPITAL, during the winter and summer sessions. The fee for the whole course is ten guineas. The class is not confined to Students of the Hospital.—For further particulars, apply to the Dean, Guy's Hospital, Southwark, S.E.

University College, London.

ORGANIC CHEMISTRY.

Assistant Professor—H. FORSTER MORLEY, M.A., D.Sc.

The following Courses of Lectures will be given in May, June, and July:—(*a*) Elementary; Tuesdays, Wednesdays, and Fridays, at 11. (*b*) Special Course, including subjects required by candidates for Int. M.B.; 3 lectures a week. (*c*) Advanced, including the more important results of recent research in organic chemistry, and in the study of the physical constants of organic bodies; 2 lectures a week. Dates of beginning: (*a*) May 3rd; (*b*) May 4th, at 9 A.M.; (*c*) April 19th, at 9 A.M.

J. M. HORSBURGH, M.A., Secretary.

Research Scholarships of the Grocers' COMPANY.

The following Lectures on "Malarial" Fevers will be given, by permission of the Board of Managers, in the theatre of the London Institution, Finsbury-circus, by W. North, Esq., one of the Company's Research Scholars.

LECTURE I.

Monday, April 18th, 5 P.M. Subject: Their Distribution, and the general conditions under which they prevail. History of them in the province of Rome.

LECTURE II.

Monday, April 25th, 5 P.M. Subject: Local Conditions affecting their distribution as studied in the province of Rome.

LECTURE III.

Thursday, April 28th, 5 P.M. Subject: Recent Researches into their otiology and pathology. The possibility of prevention in the individual, and of improving the conditions of malarious countries.

University of Durham College of MEDICINE, Newcastle-upon-Tyne.

The SUMMER SESSION will commence on Monday, May 2nd.

LICENCES AND DEGREES IN MEDICINE, SURGERY, AND SANITARY SCIENCE.—Three Licences and four Degrees are conferred by the University of Durham—viz., Licences in Medicine, in Surgery, and in Sanitary Science; the Degrees of Bachelor in Medicine, Master in Surgery, Bachelor in Surgery, and Doctor in Medicine. Attendance at the University of Durham College of Medicine during one of the four years of professional study, or subsequently to qualification elsewhere, is required as part of the curriculum for the Degrees, except in the case of Practitioners of more than fifteen years' standing, who have attained the age of forty years, who can obtain the Degree after examination only.

The first and second examinations for the Degree of M.B. may be passed prior to attendance at Newcastle.

The extra Preliminary in Arts may be passed at any time previously to the candidate's entry for his Final Examination for the Degree. Candidates who have passed the First Examination of the Conjoint Board in England of the Royal Colleges of Physicians and Surgeons will be admitted to the Second Examination for the Degree of M.B. without further examination, except in Chemistry, with Chemical Physics, and Botany with Medical Botany. Candidates who may pass the First and Second Examination for the Degree of M.B. will be exempt from the First and Second Examinations of the Conjoint Board.

SCHOLARSHIPS, &c.—A University of Durham Scholarship, value £100, for Proficiency in Arts, awarded annually to Students in their first year only. The Dickinson Scholarship, value £15, annually, together with a Gold Medal, for Medicine, Surgery, Midwifery, and Pathology. The Tulloch Scholarship, value £20, annually, for Anatomy, Physiology, and Chemistry. The Charlton Scholarship, value £35, annually, for Medicine. The Gibb Scholarship, value £25, annually, for Pathology. The Goyder Memorial Scholarship (at the Infirmary, Newcastle), value £16, for proficiency in Clinical Medicine and Clinical Surgery. At the end of each Session a Silver Medal and Certificates of Honour are awarded in each of the regular classes. An Assistant Curator of the Museum is annually appointed from among the Senior Students, and receives an honorarium of £12. Four Assistant Demonstrators of Anatomy (each receiving an honorarium of £5), two Assistant Physiologists, and two Pathological Assistants are also elected. Four Resident Assistants, three non-resident Clerks, and sixteen non-resident Dressers are chosen every three months.—Further particulars with regard to Examinations may be obtained from Luke Armstrong, M.D., 1, Eldon-square, Newcastle-upon-Tyne; or, on all other matters connected with the College, from Mr. Henry E. Armstrong, College of Medicine, Newcastle-upon-Tyne.

The Yorkshire College, Leeds: Medical

Department.—The Fifty-sixth SUMMER SESSION of the Leeds School of Medicine will begin on May 2nd. Prospectus free from the Registrar.

University College, Bristol,

MEDICAL SCHOOL.

The Summer Session will commence on Monday, May 2nd. Prospectuses may be obtained on application to

E. MARKHAM SKERRITT, M.D., Dean.

VICTORIA UNIVERSITY.

University College, Liverpool.

MEDICAL FACULTY.

The SUMMER TERM will COMMENCE on MONDAY, MAY 2ND.

LECTURES AND CLASSES.

Materia Medica	Dr. Carter.
Medical Jurisprudence	Mr. Paul.
Botany	Dr. Shearer.
Practical Chemistry	Dr. Campbell Brown.
Operative Surgery	Mr. Rushton Parker.
Practical Pathology	Dr. Davidson and Dr. Barron.
Practical Anatomy	Mr. Banks and Dr. Ross.
Practical Physiology	Dr. Caton and Mr. Larkin.
Hygiene	Dr. Hope.
Comparative Anatomy	Dr. Herdman.
Physics	Dr. Oliver Lodge.

DENTAL LECTURES.

Surgery	Mr. Phillips.	Anatomy	Mr. Paul.
Mechanics	Mr. Councell.	Metallurgy	Mr. Royston.

For Prospectus and information apply to the Vice-Dean, Mr. PAUL, 38, Rodney-street.

Owens College, Victoria University, MANCHESTER.

MEDICAL DEPARTMENT.—SUMMER SESSION.

Principal—J. G. GREENWOOD, LL.D.

Dean—Professor ALFRED H. YOUNG, M.B., F.R.C.S.

PROFESSORS AND LECTURERS.

Practical Anatomy—Professor Alfred H. Young, M.B., F.R.C.S.
Practical Histology—Brackenbury Professor, William Sterling, M.D., D.Sc.
Practical Chemistry—Professor Harold B. Dixon, M.A., F.R.S.
Botany—Professor W. C. Williamson, LL.D., F.R.S.
Zoology and Embryology—Professor A. Milnes Marshall, M.D., M.A., D.Sc., F.R.S.
Comparative Osteology—C. Herbert Hurst.
Materia Medica and Therapeutics; Practical Pharmacy—Professor D. J. Leech, M.D., F.R.C.P.
Practical Morbid Histology—Professor Julius Dreschfeld, M.D., F.R.C.P.
Operative Surgery—Thos. Jones, M.B., B.S., F.R.C.S.
Practical Surgical Pathology—Alfred H. Young, M.B., F.R.C.S.
Obstetrics and Gynæcology—Professor Charles J. Cullingworth, M.D., M.R.C.P.
Clinical Obstetrics and Gynæcology—Professor Charles J. Cullingworth, M.D., M.R.C.P.; D. Lloyd Roberts, M.D., F.R.C.P., F.R.S.E.
Diseases of Children—Henry Ashby, M.D., M.R.C.P.
Medical Jurisprudence and Practical Toxicology—J. Dixon Mann, M.D., M.R.C.P.
Hygiene—Arthur Ransome, M.D., M.A., F.R.S.
Mental Diseases—George Wm. Mould, M.R.C.S.
Ophthalmology—David Little, M.D.
Clinical Ophthalmology—David Little, M.D.; Charles E. Glascott, M.D.
Dental Surgery—Leonard Matheson, L.D.S.
Dental Anatomy and Physiology—A. M. Paterson, M.D., M.R.C.S.
Dental Metallurgy—C. A. Burghardt, Ph.D.

With Assistant Lecturers in all the principal subjects.

The Session commences May 2nd.

The Classes at the College qualify for Degrees in the Victoria University, for many of the Degree Examinations of the University of London; and for the Diplomas of the Royal Colleges of Physicians and Surgeons of London, &c. &c.

Prospectus will be forwarded on application to the Registrar.

HENRY WM. HOLDER, M.A., Registrar.

"MORNINGSIDE," LATON ROAD, HASTINGS.

HOME SCHOOL

For Delicate Girls.

Speech for the Dumb.—The Associa-

TION for the ORAL INSTRUCTION of the DEAF and DUMB, 11, Fitzroy-square, W., under the presidency of EARL GRANVILLE, K.G., educates children upon the pure Oral or German system (by which they are taught to speak and to understand what others say by means of lip-reading), and trains teachers on that system, both for public institutions and private families.

Members of the medical profession are cordially invited to visit the school and college of the Association any time by appointment, or to attend the public lessons on Wednesday afternoons, at 3 o'clock.

For terms and particulars, apply to William Van Praagh, Esq., Director, 11, Fitzroy-square, W., any morning between 11 and 1.

Digitized by Google

Clinique on Diseases of the Skin.—

Professor McCALL ANDERSON'S Clinique on Diseases of the Skin (at the Hospital for Skin Diseases, 8, Elmbank-street, Glasgow) will commence on Wednesday, May 4th, and be continued during the Summer Session every Monday and Wednesday, at half-past 2 P.M. Students enrolled at the hospital. Fee 1 guinea. The directors offer the sum of £5, to be expended in a prize or prizes to the most deserving students.

University of Edinburgh.

SUMMER SESSION, 1887.

The Summer Session will commence on Tuesday, May 3rd, 1887.

Principal—Sir WILLIAM MUIR, K.C.S.I., D.C.L., LL.D.

The Classes for the different Branches of Study will be opened as follows:—

Classes.	*Days of Opening and Hours of Attendance.*	*Professors.*
Medical Jurisprudence (for Law and Medical Students)	Tues., May 3, 11 A.M.	Prof. Sir Douglas Maclagan.
Botany	Tues., May 3, 8 A.M.	Prof. Dickson.
Practical Botany and Vegetable Histology	Tues., May 3, 9 A.M.	
Field Demonstrations on Saturdays.		
Obstetrical and Gynæcological Operations (Tuesday and Friday)	Tues., May 3, 10 A.M.	Prof. Simpson.
Practical Materia Medica (including Pharmacy) ...	Tues., May 3, 10 A.M.	Professor Thomas R. Fraser.
Practical Chemistry ...	Tues., May 3, 9 45 and 11 A.M...	Prof. Crum Brown.
Practical Morbid Anatomy and Pathology	Tues., May 3, 11 A.M.	Prof. Greenfield.
Anatomical Demonstrations	Wed., May 4, 11 A.M. daily	Prof. Sir William Turner, and David Hepburn, M.B., Demonstrator.
Practical Anatomy... ...	Tues., May 3, daily.	
Clinical Surgery (Royal Infirmary, Mon. & Thurs.)	Thurs., May 5, 12 noon.	Prof. Annandale.
Clinical Medicine (Royal Infirmary, Tues. and Frid.)	Tues., May 3, 12 to 2 P.M.	Profs. Grainger Stewart, T. R. Fraser, and Greenfield. Prof. Simpson, on Diseases of Women.
Chemistry (Organic) Advanced Class (Tues., Wed., and Thurs.) ...	Tues., May 3, 1 P.M.	Prof. Crum Brown.
Natural History	Tues., May 3, 2 P.M.	Prof. Ewart.
Practical Natural History	Tues., May 3, 3 P.M.	
Practical Physiology, including Histology ...	Tues., May 3, 2 P.M.	Prof. Rutherford.
Operative Surgery and Surgical Appliances.	Tues., May 3, 4 P.M.	Prof. Chiene.
Practical Hygiene ...	Tues., May 3, 2 P.M.	Prof. Sir Douglas Maclagan.
		Lecturers.
Mental Diseases, with Practical Instruction at Morningside Asylum. (Mon., Wed., Frid.)	Wed, May 4, 3 P.M.	Thomas S. Clouston, M.D.
Diseases of the Eye... ...	Wed., May 4, 9 A.M.	D. Argyll Robertson, M.D.
Clinical Instruction on Diseases of Children at Royal Hospital for Sick Children.	Tues., May 3, 10 A.M.	James Andrew, M.D. James Carmichael, M.D.
Comparative Embryology	Tues., May 3, 3 P.M.	Mr. George Brook.

Royal Infirmary, daily, at noon.

Summer Session ends July 22nd. Graduation Ceremonial in Medicine, &c., Monday, August 1st.

The classes in the Faculty of Medicine, except Botany, Natural History, Clinical Medicine, and Clinical Surgery, meet in the University New Buildings.

Faculty of Arts.—Tutorial Classes in Latin, Greek, Mathematics, Natural Philosophy, Logic and Psychology, and Moral Philosophy, will meet on Tuesday, May 3rd. Fees payable to the Class Assistants.

Practical instruction is afforded in laboratories furnished with all the necessary appliances, and in Tutorial and Practical Classes in connexion with the above chairs, and under the superintendence of the professors.

Information relative to Matriculation and the Curricula of Study for Degrees, Examinations, &c., may be obtained on application to the respective Deans, or at the Secretary's Office, and full details are also given in the University Calendar, published by James Thin, 55, South Bridge. By authority of the Senatus.

March 1887. JOHN KIRKPATRICK, Sec. Sen. Acad.

Edinburgh.— Students.— Boarding.—

A Physician residing in a healthy locality within a short distance from the University and Hospitals, &c., can receive one or two Students attending classes during the summer session, beginning early in May. Studies superintended and control maintained over juniors to prevent idleness. Home comforts ensured.—Particulars forwarded on addressing Physician, care of Messrs. Keith & Co., Advertising Agents, 65, George-street, Edinburgh.

COLWYN BAY, NORTH WALES.

CLIMATE MILD, DRY, BRACING.

First-class SCHOOL for Young Gentlewomen. Most highly recommended by several physicians. Principal, Miss BARLOW.

Individual attention is given, and a healthy, natural, moral tone is aimed at, a tone befitting GOOD WOMEN.

Colwyn Bay has lovely country walks, good sea bathing, and mild winters.

King Edward VI.'s School, Berkhamsted,

Herts, twenty-eight miles from Euston. Good Scholarships and Exhibitions. Laboratory, heated Swimming Bath, Fives Courts, Workshops, &c. £52 per annum.—Address, Head Master.

Education.—To Professional Men of

Limited Income.—A few BOYS, sons of the above, are admitted from time to time into a well-known school of high tone, on greatly reduced fees.—For full particulars, address, in strict confidence, Mu, care of Messrs. Relfe Brothers, 6, Charterhouse-buildings, Aldersgate, London, E.C.

Epsom College Preparatory School.—

For Sons of Medical Men. Under the patronage of the Council.—Mr. Jeffery, twenty years Assistant-master, prepares boys, under fourteen, for Epsom College. Latin, Greek, German, French, thorough English, Arithmetic, Algebra, Euclid. Cricket and football during the seasons.—Prospectus of J. Jeffery, Parade, Epsom.

Oral Education of the Deaf.—Mr. H. N.

DIXON, M.A. Lond. and Cambridge, F.L.S., gives a thorough and high class education to deaf children, based upon the Oral Method.

For Prospectus, apply to H. N. Dixon, 25, St. Paul's-road, Northampton.

DEFECTS OF SPEECH.

Mr. WILLIAM VAN PRAAGH'S System for the Cure of all Defects of Speech, both ACQUIRED and CONGENITAL.

For information, apply to Mr. William Van Praagh, 11, Fitzroy-square, London, W. Personal interviews by appointment.

Deaf and Dumb Children of the higher

Classes educated on a Pure Oral System. Private and select school for limited number. Special home comforts.—Address, Harry W. White (formerly Vice-principal Ealing Training College for Teachers of the Deaf), 115, Holland-road, Kensington. Next Term April 25th. "By this method alone is the intellect of the mute enabled to travel beyond the range of a few who are skilled in the manual sign language, and to converse freely with all."—THE LANCET, July 11th, 1885.

College for Daughters of Medical

MEN.

Pelican House College (in connexion with Pelican House School), Grove-park, Denmark-hill, S.E., for the Education of the Daughters of Medical Men, at fixed, inclusive, and moderate terms, varying according to age, as at the Epsom College for Boys.

The educational advantages will be equal to those of the best high schools; but the College, being designed for the Daughters of Professional Men only, will offer the further desideratum of suitable companionship.

Applications must be made to the Secretary, Captain Pead, Ivyhurst, Dulwich-grove, Dulwich, S.E.

Massage.—Lectures and Demonstra-

TIONS at the West-end HOSPITAL for DISEASES of the NERVOUS SYSTEM, Welbeck-street, W.—Particulars, apply to Matron.

MASSAGE AND ELECTRICAL TREATMENT.

LECTURES and DEMONSTRATIONS will be delivered at the SCHOOL of MASSAGE and ELECTRICITY, West-End Hospital for Paralysis, Epilepsy, and Diseases of the Nervous System, 73, Welbeck-street, Cavendish-square, W., by HERBERT TIBBITS, M.D., F.R.C.P. Edin., and THOMAS STRETCH DOWSE, M.D., F.R.C.P. Edin., Physicians to the Hospital. Ladies and Nurses admitted to the School for training. Trained Masseuses and Electricians sent to all parts of the United Kingdom. For particulars, apply to the Lady Superintendent.

By order.

H. ALEX. DOWSE, Hon. Sec.

ADDRESS AND TESTIMONIAL

TO

DR. B. BURKE KENNEDY.

At a meeting held at the Shelbourne Hotel, Sir CHARLES CAMERON in the chair, it was resolved to open a "Defence Fund" to pay the heavy legal expenses incurred by Dr. BERNARD BURKE KENNEDY, Resident Surgeon, Mercer's Hospital, against whom a charge of manslaughter was recently brought, and which charge was proved to be groundless, before a legal tribunal, on the evidence given for the prosecution, the jury having stopped the case, returned a verdict of acquittal, and added the following rider:—"*We consider that, according to the evidence, Dr. Kennedy should not have been subjected to the hardship of a prosecution.*"

Mr. Justice Murphy expressed his concurrence with the view taken by the jury. Dr. KENNEDY would not have been warranted in leaving a delirious man amongst the other patients in the ward, for if anything had, through his doing so, happened to the other patients, censure would undoubtedly be passed on him. They could not say on the evidence that he had used any unnecessary violence. No complaint had been made to the hospital authorities. This case was brought against Dr. KENNEDY by witnesses being got here and there, and suggestions being made; however, it was much the best thing for Dr. KENNEDY that the open investigation in this court should have been made.

The man died in August, 1886. The Legal Process was not commenced until January, 1887.

COMMITTEE.

Sir JAMES PAGET, Bart.
Sir GEORGE BURROWS, Bart.
Sir PRESCOTT G. HEWETT, Bart.

near Maidstone.—PRIVATE PATIENTS are admitted into this Asylum at the rate of seventeen shillings a week, everything included.—For particulars apply to F. Pritchard Davies, Superintendent.

Mental and Nervous.—A charming

HOME, with every comfort and careful supervision, in the private house of a married medical man of large experience, in S.W. suburb. Beautiful garden, tennis lawn, billiard table, carriage and horses. Highest references.—Address, A. B., THE LANCET Office, 423, Strand, W.C.

Harpenden Hall, Herts.—Twenty-five

miles from London, on the Midland Railway. Established 1846 for the treatment and cure of Ladies mentally afflicted. Carriage exercise, lawn tennis, and other amusements are provided. Four *quiet* ladies can be taken, at one guinea a week.—For terms, &c., apply to A. MacLean, Proprietor and Medical Superintendent.

Stretton House Private Asylum, Church

Stretton, Salop. (For Gentlemen only.)—This Asylum possesses many natural advantages: beautiful scenery, bracing atmosphere, extensive grounds, and facilities for every sort of recreation.
Special care and treatment of Insanity arising from or complicated with Inebriety. Apply to CAMPBELL HYSLOP, Supt.
Dr. CECIL A. P. OSBURNE, Medical Consultant.

Wye House Asylum, Buxton, Derby-

shire, for the Middle and Upper Classes of BOTH SEXES, is beautifully situated in the healthy and bracing climate of the Derbyshire hills, and is directly accessible by the Midland and the London and North-Western Railways.—For terms and other particulars address the Resident Physician and Proprietor, Dr. F. K. DICKSON.

Barnwood House Hospital for the

INSANE of the MIDDLE and UPPER CLASSES, Barnwood, near Gloucester.—An Institution for the care and treatment of Patients of both sexes, who can have private rooms and special attendants, as well as the use of general sitting-rooms, at moderate rates of payment.
Patients can also be accommodated in detached villas, and in the Branch Convalescent Establishment on the hills.
Information as to terms, &c., may be obtained on application to Dr. Needham, the Medical Superintendent.

Dundee Royal Asylum, West-green.—

This new and commodious building, recently erected about four miles from Dundee, in a healthy situation, and commanding extensive and beautiful views of the Valley of the Tay, affords superior accommodation for Private Patients, at low rates of board.
Dr. Mitchell, H.M. Commissioner in Lunacy, reports "the accommodation provided for Private Patients is excellent, both as regards those who pay from 15s. to 21s. per week and as regards those who pay higher rates, and the amusements are frequent and varied."
For further information, apply to Dr. Rorie at the Asylum.

Haydock Lodge Retreat, for the Care

and Cure of Persons of Unsound Mind, Ashton, near Newton-le-Willows, Lancashire, about two miles from Newton Bridge Station on the London and North-Western Railway. Terms: First-class patients from £1 10s. to £6 6s. per week, according to accommodation, attendance, &c.; middle-class from £1 1s. to £1 10s. per week, according to the nature of the case. Suites of private rooms for a gentleman and a lady now at liberty.—Apply to E. H. Beaman, M.R.C.S.E. and L.S.A. Lond., resident medical proprietor, or to the Medical Superintendent.

St. Andrew's Hospital for Mental

DISEASES, NORTHAMPTON.
For the Middle and Upper Classes only.
President—The Right Honourable the Earl SPENCER, K.G.
Chairman of the Committee of Management—The Most Honourable the Marquis of NORTHAMPTON, K.G.
The main object of this Institution is to provide accommodation and comforts suitable to the former social and present mental condition of persons belonging to the Upper and Middle Classes *at moderate rates of payment.*
The terms of admission vary from £1 5s. to £3 3s. per week, according to the requirements of the case.
These terms may be reduced, after the first quarter, if the friends can satisfy the Committee of Management that so much cannot be afforded.
Patients paying higher rates can have private rooms, and special attendants, carriages, horses, &c.
There are also houses at Moulton-park, a branch establishment, two miles from the Hospital, but in telephonic communication; and a sea-side house, to which Patients can be sent.
For further information apply to the Medical Superintendent.

Crichton Royal Institution, Dumfries,

endowed by the late JAMES CRICHTON, Esq., of Friar's Carse, and Incorporated by Act of Parliament, as a Hospital for the Insane and a Home for Mental and Nervous Invalids of the Higher and Middle Classes.
The Trustees and Directors of the Crichton Royal Institution, in order to meet the requirements of a large section of the community, have instituted an INTERMEDIATE DEPARTMENT *for the care and treatment of persons of unsound mind, at rates of board of £40 and £52 per annum.*
Information regarding higher class rates to be had on application.
Communications to be addressed to Dr. Rutherford, Medical Superintendent.

Hendon Grove Asylum for Ladies,

Hendon, Middlesex. Beautifully situated in extensive grounds and a park, half a mile from the Hendon Station on the Midland Railway, and less than six miles from Hyde and Regent's Parks. Inclusive terms from £4 4s. a week.—Apply to Dr. H. HICKS, Resident Physician and Proprietor.

THE COPPICE, NOTTINGHAM.

HOSPITAL FOR THE INSANE OF THE MIDDLE AND UPPER CLASSES.
President—The Right Hon. the Earl Manvers.
This Institution having been considerably enlarged, there are now Vacancies for Patients of both sexes, at moderate rates of payment. Particulars as to terms, &c., may be obtained from Dr. TATE, Medical Superintendent.

Grove House, All Stretton, Church

STRETTON, SHROPSHIRE.
A Private Asylum for the Care and Treatment of a limited number of LADIES of the Middle and Upper Classes.
For terms and particulars apply to Mrs. McLintock (widow of the late Dr. McLintock), the Resident Proprietress, or to the Medical Superintendent.

Private Home for the Treatment of

INSANE LADIES,
ASHBROOK HALL, HOLLINGTON,

within half an hour's walk of St. Leonards-on-Sea, conducted by the Widow of the late Samuel Hitch, M.D., formerly of Sandywell-park near Cheltenham, for many years Physician to the General Lunatic Asylum for the County of Gloucester.

Station: Warrior-square, St. Leonards. Telegraph Office: Silverhill.
For particulars and terms, apply to
Mrs. LETITIA A. HITCH.

Northgrove, Hawkhurst, Kent (1839).

This Asylum, situate midway between Tunbridge Wells and Hastings, stands in extensive grounds, and has an extra house for special cases and convalescents; also a Cottage Hospital. This Asylum is an excellent home for middle-aged and elderly patients, being replete with all the comforts and advantages necessary for the treatment of mental diseases. Patients can keep their own carriages and horses. Terms strictly moderate. Railway station: Etchingham, S.E.R.—For full particulars, apply to F.R.C.P., Physician-Superintendent.

FOR MENTAL AND NERVOUS INVALIDS.

West Malling Place, Kent.—A Family

MANSION, standing on its own extensive grounds, beautifully and healthfully situated among picturesque scenery, for Residence, Care, and Home Treatment of a limited number of ladies and gentlemen. Carriage exercise, billiards, lawn-tennis, seaside residence. Twenty-eight miles by road from London. Station on L.C. & Dover Railway. Terms strictly moderate.—Letter or telegram addressed to Dr. Adam, Resident Physician, will receive immediate attention.

MAVISBANK HOUSE, near Edinburgh.

A Hospital for the Insane, and a Home for Mental and Nervous Invalids.

Chairman of the Board of Direction—The Right Honourable Sir Thomas Clark, Bart., Lord Provost of the City of Edinburgh.

Mavisbank House is about six miles from Edinburgh, in the beautiful neighbourhood of Roslin. It is a comfortably furnished old mansion, containing large and handsome dining- and drawing-rooms, billiard-room, library, conservatory, and private parlours.

The estate is upwards of 120 acres in extent, with stabling, large flower and fruit gardens, hot houses, and vineries.

The Directors have arranged to receive a limited number of patients at ONE GUINEA A WEEK, who will reside in the comfortable farm house on the estate. They will receive careful supervision and every comfort.

The terms are inclusive, clothing only excepted.

Mavisbank House is five minutes' walk from Polton Station, on the North British Railway.

For further information apply to the Resident Medical Superintendent, Dr. KEAY, Mavisbank House, Polton, Midlothian.

Chester General Infirmary.—Wanted,

a VISITING SURGEON for this Institution. Unexceptionable testimonials will be required of moral conduct. The candidates must possess a double qualification, and be duly registered. Salary to commence at £80 per annum, with residence and maintenance in the house.

Descriptive pamphlet of the Association, with names of the Directors, sent on application.

Managing Director: G. B. STOCKER.

(No. 1.) LONDON SUBURB.—High-class PRACTICE of over £1200 per annum; all good-class patients; good fees; very little night-work. Premium £1800 to £2000 cash, according to length of introduction (six to eighteen months). Large house in a good position.

(No. 2.) LONDON SUBURB.—Very good middle-class PRACTICE of £1050 per annum. Fees mostly 5s.; Midwifery £3 3s. Expenses light. Large house, well situated. Premium £1500 cash.

(No. 3.) SOUTH-WESTERN COUNTY.—Country town PRACTICE of over £2000 per annum. Easily worked. Very good house, stabling, and garden. The Practice and neighbourhood offer many attractions, and nearly two years' purchase will be required, with ample introduction.

(No. 4.) WESTERN COUNTY.—A good-class PRACTICE of nearly £1100 per annum. Two horses required; no assistant. Rent of fair-sized house, with stabling, gardens, &c., £45. Premium £1250.

(No. 5.) SOUTH COAST.—In a large and first-rate town, a high-class PRACTICE of £1000 per annum. Old established; non-dispensing. Excellent freehold house, adapted to receiving resident patients, which must be bought. Hardly any Midwifery or night-work.

(No. 6.) LONDON SUBURB.—PARTNERSHIP in a Practice of £3000. A third or fourth share will be sold at two years' purchase to an Oxford or Cambridge man.

(No. 7.) HOME COUNTIES.—Unopposed Country PRACTICE of about £700 per annum, including appointments. Near a good town. Excellent house. Premium for goodwill, with introduction as desired, £1000.

(No. 8.) SOUTH.—Good COUNTRY PRACTICE in one of the Home counties. Receipts last year over £800. No Union appointment. Introduction as desired. Beautiful district. Good society.

(No. 9.) MIDLANDS.—Old-established unopposed PRACTICE of over £425 per annum, including nearly £150 from appointments. First-rate hunting district. Expenses light. Small house. Premium £400.

(No. 10.) LONDON.—Half-share in a well-established Dispensary PRACTICE of about £1200 per annum. Would occupy only three days a week, and admit of Private Practice in addition. Premium £900.

(No. 11.) LONDON SUBURB.—PARTNERSHIP in a good Practice, with appointments, in a pleasant suburb. Share would yield at first £300 per annum. The opening is suited only to a well-qualified man, who must be energetic (though the work would not be hard at first), and have some private income.

(No. 12.) SCOTLAND.—In a large town, a high-class PRACTICE of £1000 per annum. Good fees. No Midwifery or night-work. House well and pleasantly situated. Price £700.

(No. 13.) SEA COAST, in a good town, a mixed PRACTICE of over £1200 per annum, with a year's partnership introduction. Premium one and a half year's receipts.

(No. 14.) MIDLANDS.—Old-established unopposed Country PRACTICE of £450 per annum, including over £200 from appointments. Practice very easily worked; hardly any Midwifery or night-work; no long distances. Rent of house, with field, £60. Premium one and a half year's income.

(No. 15.) HOME COUNTIES.—Increasing PRACTICE of over £300 per annum, in a town within forty minutes of London. Unqualified Assistant kept; other expenses very light. Rent of house £35. Vendor has held the Practice ten years. Premium, to include drugs, £800.

(No. 16.) SOUTHERN COUNTY.—Share (about £600 per annum gross) of a Country PRACTICE for £500. Rent of house £35.

(No. 17.) PRACTICE IN A NORTHERN MANUFACTURING TOWN of £1200 per annum. Excellent house. A purchaser will require a capital of about £2000, and will at once receive an income of the amount stated.

ASSISTANTS AND LOCUM TENENS PROVIDED.

Telegraph address: "Triform, London."

Apply Sec., Med., &c., Assn., Ld., 8, Lancaster-place, Strand.

MEDICAL PARTNERSHIP AND CONVEYANCING AGENCY.
1, ADAM-STREET, ADELPHI, W.C.

Mr. J. C. Needes begs to inform members of the Profession desirous of Disposing of their Practices that they can on application to him be promptly introduced to Successors. All matters connected with the Transfer of Practices and Partnerships, Medical Arbitrations, Valuations, &c., receive Mr. Needes' immediate personal attention, and negotiations are conducted by him in the strictest confidence.

Trustworthy LOCUM TENENS and ASSISTANTS can be had at a few hours' notice.

N.B.—No charge made to Purchasers or to Gentlemen seeking information.

In a beautiful residential district and health resort, within easy distance of Brighton, a well-established PRACTICE, worth between £400 and £500 per annum. Fees 2s. 6d. to 10s. 6d. Midwifery one to five guineas. Commodious residence, with large garden.—Apply to J. C. Needes, 1, Adam-street, Adelphi, W.C.

£800 a year.—Fifty miles south of London.—The Practice is very old established, and situate in a pretty village containing a railway station on a direct line of rail. One horse only required. Good family residence at a moderate rental. Premium one year's purchase.—Apply to J. C. Needes, 1, Adam-street, Adelphi, W.C.

Wanted, by a M.D., a good-class PRACTICE, not less than £1200 a year, situated in a provincial town. The full marketable value will be paid, and an immediate arrangement can be entered into.—Particulars received, in confidence, by J. C. Needes, 1, Adam-street, Adelphi, W.C.

Junior Partnership.—A Share yielding £300 a year (with immediate prospects of increase) is offered to a well-qualified gentleman at the usual rate of purchase. The Practice is old-established, and situated in one of the best residential suburbs of London.—Apply to J. C. Needes, 1, Adam-street, Adelphi, W.C.

Death Vacancy.—£1200 a year; appointments £500.—An unopposed PRACTICE, held by late incumbent over forty years, situate within seventy miles of London. An efficient qualified gentleman carrying on the Practice, who has been associated with it for some time past. As there is no opposition within six miles, the whole of the Practice can reasonably be expected to be transferred to an active gentleman. A portion of the premium can be paid by instalments.—Apply to J. C. Needes, 1, Adam-st., Adelphi, W.C.

Yorkshire.—In a small town in a good hunting district, a well-established PRACTICE worth about £450 per annum. Several appointments held. Good-class patients; forty cases of Midwifery yearly. This investment offers good prospects of future increase, the other medical man in the town (who has a good practice) being advanced in years.—Apply to J. C. Needes, 1, Adam-street, Adelphi, W.C.

£1500 a year.—Within an hour of London, a very old established PRACTICE, averaging for some years past the above amount. The connexion is situate in a small town with good district around, and there is every reason to believe it could be transferred to a doubly qualified energetic gentleman not less than thirty years of age, as the opposition, as compared with the number of inhabitants, is below the average. Reference can be given to several gentlemen on the staff of one of the London hospitals. A partnership introduction given to meet wishes of purchaser.—Apply to J. C. Needes, 1, Adam-street, Adelphi, W.C.

Canada, near Niagara.—£1250 per annum; unopposed, the nearest Medical Man residing eight miles distant. Railway station in place. Area of Practice about ten miles. Expenses small. The house, which is suitable for a family, and stands in two acres of ground, is vendor's freehold, valued at £700, and will be disposed of, together with the Practice, for the moderate sum of 1000 guineas, of which 500 guineas can remain on mortgage. Climate mild. Reference given to a Medical Man in London, who can give the fullest information.—Apply to J. C. Needes, 1, Adam-street, Adelphi, W.C.

London, S.W.—A mixed Private and Dispensary PRACTICE, the cash receipts of which last year were £630, inclusive of appointments worth £140, which may reasonably be expected to be transferred to a doubly qualified successor. Present incumbent has been in delicate health, and has avoided nearly all night-work.—Apply to J. C. Needes, 1, Adam-street, Adelphi, W.C.

West of England.—£900 a year.—In a large town, an old-established and lucrative PRACTICE, averaging over £900 per annum. The connexion is nearly all good middle-class, and the Visiting fees range from 2s. 6d. to 10s., exclusive of medicine. Very easily worked, only one horse required. Convenient family residence can be secured by the successor at a moderate rental. Premium one year's purchase.—Apply to J. C. Needes, 1, Adam-street, Adelphi, W.C.

Messrs. H. Wilson and Son,

26, CHARLES-STREET, ST. JAMES'S-SQUARE, S.W.
Established half a century.
QUALIFIED ASSISTANTS PROVIDED.
LOCUM TENENS.—Suitable qualified Gentlemen can be engaged at a moment's notice.

1. N.W. Suburbs.—A well-established PRACTICE, about £600 per annum; has been conducted by the present practitioner about ten years, who can give most satisfactory reasons for relinquishing. A good house; rent £80. It is proposed to give three months' introduction. Premium one year's purchase. This is a good opportunity for any active practitioner seeking a connexion capable of increase.

2. In a leading thoroughfare, within two miles of the Bank, a NUCLEUS, about £250 to £300, including an appointment of £60. A good house, been the residence of a medical practitioner for half a century.

3. On easy terms, a mixed-class PRACTICE, chiefly Catholic, for immediate disposal, with short introduction, at present worth about £400 per annum, capable of great increase. Good opportunity for an active Catholic gentleman. Easy terms can be arranged, to include furniture, drugs, and surgery fittings.

4. Partnership.—London Suburbs.—A JUNIOR PARTNER required in a mixed-class Practice, in a populous and increasing district. Present amount of income £1500 per annum. The incoming Partner should be well up in Midwifery, there being some 200 cases a year. Working expenses light, and a convenient house can be obtained. The Practice has been conducted by the present practitioner some twelve years.

5. Seaside Town.—A General Practice, which produced in cash last year £333 and booked £371. A semi-detached villa residence held at a moderate rental; working expenses very light. Midwifery from 1 guinea; about sixty cases a year. This is suitable for any active Practitioner wishing a Practice capable of increase. The town is much frequented by visitors, and an improving one. An efficient introduction; good educational advantages.

6. W.C. District.—A General Practice, about £250 per annum. Good house, held on lease. Premium £250. A good introduction given.

7. In a good residential district, four miles from a large and important town. Income between £600 and £700 per annum, which can be very considerably extended by an active gentleman fond of work. Good detached house; large garden and stabling. Good class of patients. No Union or Clubs.

8. In a large town in the North of England.—PRACTICE for disposal in consequence of the present practitioner being desirous of retiring for a time from the profession. Income about £1600 per annum, including appointments. A good house, stabling, and every convenience for a professional residence. Premium one year's purchase; part can remain over provided security is given. The vendor has conducted it twenty years, and has saved money sufficient to retire upon.

9. Devonshire.—Partnership Introduction. A General Practitioner who has conducted a Practice situate in a town for some years, and which is producing about £500 per annum, including appointments about £170. Good house; rent £45. Midwifery from £2 2s. It is proposed to give twelve or eighteen months' introduction.

10. Nucleus.—In a good and increasing suburban district, S.W. A good detached house, with garden. An introduction can be given to many good families. Suitable for a gentleman with private means wishing a good-class Practice capable of increase.

11. Near the Crystal Palace.—A NUCLEUS, about £200 per annum. Convenient house in a main thoroughfare; rent £56. An introduction can be given to many good families.

PRACTICES REQUIRED.

Practice wanted, by a Gentleman fully qualified, in a country town within sixty miles of Town. Premium can be paid down.—Apply, H. S.

Practice wanted, by a Gentleman (married), F.R.C.S. Eng., L.R.C.P., who wishes to purchase a PRACTICE, £500 to £700 per annum, in a country town not less than 3000 population.—Apply, B. F.

Practice wanted in the Eastern Counties, by a Gentleman, M.B., M.R.C.S., &c., in a town, from £500 to £700. Is prepared to carry out an immediate arrangement.—Address, in confidence, M.B.

MEDICAL VACANCIES.

Qualified Resident.—Eastern County, £70 to £80; Midland Counties, £60; plenty of time for reading.

A qualified Practitioner wanted to conduct an open Surgery in the S.W. district. Personal application only.

Mrs. Needes' Medical Agency Offices,

9, EUSTON-ROAD, N.W.
(Opposite Great Northern Railway Station, King's-cross.)
Established 1860.

The Business carried on for the past eighteen years by Mrs. Needes (widow of J. W. Needes), at 17, Belgrave-street, has been removed to the above address, where it is conducted by her as usual. No connexion with any other agency advertised under the same name, this being the original business established by her late husband in 1860.

LOCUM TENENS.—Reliable Gentlemen always on the books.
ASSISTANTS provided free of expense to principals.
No charge made to purchasers.

Twelve Months' Partnership Introduction given to an old-established good-class PRACTICE, situate in a pleasant country town, and held by the incumbent many years. The receipts last year amounted to over £1150, including appointments. Expenses moderate. Commodious family residence to be had on lease. Premium required, about one and a half year's purchase. £800 to be paid on entry.

For immediate Disposal, the Vendor having other engagements, an old-established, unopposed country PRACTICE, with freehold residence standing in about three-quarters of an acre of ground. Annual income £500, inclusive of appointments of £250. About £1250 will be required, part of which may remain on mortgage. The Practice is situate in a pleasant district within 100 miles.

London. — Old-established Practice, situate in a good open district, and held by the vendor many years. The income, including valuable appointments, transferable to a suitable man, averages over £700 per annum. About forty cases of Midwifery yearly, from a guinea. Comfortable house, fitted more especially for a bachelor. Premium, with an efficient introduction, one year's purchase. Horse and brougham kept, but not necessary.

London. — General Practice (chiefly ready money), held by the incumbent many years, and returning about £600 per annum. Capable of considerable increase by an active gentleman. Good house, held at a moderate rental. An efficient introduction given and less than a year's purchase accepted.

Cathedral Town.—Small and increasing PRACTICE of about £100 per annum, including £80 from appointments. Visits 2s. 6d. to £1 1s. No Midwifery under a guinea. Good society, with educational advantages. Convenient house, rent £50. An excellent opening for a well-qualified active gentleman commencing practice, there being plenty of scope.

Midland.—Rapidly increasing Practice, situate in a rising town, and realising nearly £650 per annum, including £250 from transferable appointments. There are only three other medical men in the district, to a population of over 15,000, and an active man, well up in Midwifery, would find this an excellent opportunity for practice. Premium, with six months' introduction, £600.

Required, by a married Gentleman, of independent means, a good-class PRACTICE in a London suburb or at the Seaside. South or West coast preferred. Income from £600 to £800. A comfortable but not large house necessary.

Required, a genuine Country Practice, unopposed preferred, of from £500 to £600 a year, with appointments, good house and garden, and not too far from a railway station. Would prefer South or West, but has no particular objection as to locality.

Required, a Practice of about £800 a year, in a country or seaside district. Lancashire preferred. Or would entertain a Partnership, with smaller income, in a provincial town. Advertiser is ready to enter upon an investment at once.

Required, Partnership, or long Introduction to a good-class Practice, in the W. or S.W. district of London. Income from £400 up to £800. Advertiser is accustomed to the best society, and has ample means at command.

Required, within 70 miles of London, an increasing PRACTICE of £500 upwards, with appointments, in a town preferred. Advertiser is a graduate of considerable experience, and is most anxious to invest without further delay. Means at command.

Required in the S.W. of England, or the Midlands, a good-class PRACTICE or a Partnership of from £600 to £900, in a nice town, where a Roman Catholic would be well received. Advertiser is a married graduate, age thirty-two, and can invest up to £1500.

Required, at once, a qualified resident ASSISTANT, for an extensive country Practice in South Wales. Must be able to ride. One able to speak Welsh preferred. Salary £80.—Apply to Mrs. Needes,

9, EUSTON ROAD, N.W.

Country Practice wanted, of from £600

to £900 a year. A Midland or southern county will be preferred. Any reasonable sum of money can be invested.—Apply to Messrs. Sladden, Son, & Johnson, 6, Duke-street, Adelphi, W.C.

Medical Transfer and Professional

AGENCY, 17, BLOOMSBURY-STREET, OXFORD-STREET, W.C.

Transfer of Practices and Partnerships arranged.

Locum Tenens and Assistants introduced. Reliable gentlemen, fully qualified, with unexceptionable testimonials, on the list.

No charge to purchasers or to gentlemen seeking information.

Gloucestershire.—Practice unopposed

for five miles. Good house and grounds (the old Manor-house), pleasantly situated in a lovely country; rent and taxes £19. Receipts over £200, and may be increased to between £500 and £600. Price of practice, furniture, fixtures, and drugs, £560.

London. — North. — Practice con-

veniently situated in an improving neighbourhood. Receipts in 1885 £130, but decreased last year owing to illness. £200 cash will be taken, as the vendor must go abroad. Rent £42.

South Coast.—Small Select Practice;

annual income £200, but may be largely increased. Price £150, part down and rest in easy instalments. Ample introduction given.

Suburban. — Walthamstow. — Small

PRACTICE, with plenty of scope. No immediate resident opposition. Receipts from £150 to £200. 30 guineas premium will be taken on account of illness. Rent £34.

Country unopposed Practice, in a pretty

village in Sussex. Average receipts between £350 and £400. Various Clubs, transferable, about £78. Midwifery fees up to £3 3s. Fair village house, with coachhouse, stable, and large garden; rent and taxes £35. Held by vendor for twelve years. Price £350.

Yorkshire.—Village Practice, inexpen-

sively worked, and with good scope for increase. Cash receipts £330, including transferable clubs about £60. Rent of house, coachhouse, stable, and garden, £26. Premium about £250.

Nottinghamshire.—First-class Nucleus,

with good opening. Receipts at the rate of £280. Efficient introduction, including some of the best county families. Price £100, or payment by results. Good house; rent £36. Furniture may be taken by arrangement.

Market Town (15,000 inhabitants in

town and neighbourhood).—NUCLEUS, £210s. weekly, and increasing daily. Fees 2s. 6d. at home, Visits 5s. A good opening. Price £10.

Assistantships wanted by fully qualified,

registered, and experienced gentlemen, with recent superior testimonials.

Apply to WM. HORNIBROOK, Medical Transfer and Professional Agency, 17, Bloomsbury-street, Oxford-street, W.C.

Wanted to Purchase, a West London

or Suburban PRACTICE of £500 to £1000 a year. Must be good class. Capital ready for a genuine thing. Purchaser is an Edinburgh graduate, and has been practising in Edinburgh.—Apply, Mr. G. B. Stocker, Managing Director, Medical, &c., Assn., Ld., 8, Lancaster-place, Strand, W.C.

Wanted to Purchase, a good-class

PRACTICE, town or country. Purchaser is M.R.C.S., L.S.A. (Guy's), aged thirty-five, and, having ample private means, could entertain either a large Practice or a small one (not less than £500 per annum), where there would be scope for increase.—Apply, Mr. G. B. Stocker, Managing Director, Medical, &c., Assn., Ld., 8, Lancaster-place, Strand, W.C.

To Let, Ivy House, Preston, with

large garden, stable, carriage-house, &c., the residence of the late Mr. William Shillito; a capital opening for a medical gentleman.—Apply to R. Kemp, Schoolmaster, Preston, Hull.

£50 cash.—With immediate Introduc-

tion, a NUCLEUS situated in a large Town. Advertiser retiring having succeeded to property.—Apply by letter only, to M. L., Lindore Villa, Messina-avenue, West-end-lane, London, N.W.

Furnished Ground Floor to be Let in

the best part of St. James's, comprising four rooms communicating, well furnished, and eminently suited to a medical man. Rent 150 guineas per annum.—Apply at 3, King-street, St. James's.

Southern Coast.—Good Country Prac-

TICE for Sale, with Partnership introduction, to meet the wishes of purchaser.

The Practice is old established and well known. Every investigation courted. Lowest price £900, for which vendor offers full value. No agents.—Address, F. B. J., THE LANCET Office, 423, Strand, W.C.

The British and Colonial Agency

(Limited) are instructed to Let a RESIDENCE, London, W., which has been occupied by a medical man as a consultant for a considerable time. There is an opening for General Practice, and the house can be obtained at a very low rent.—Address, No. 1065, 27, Margaret-street, Cavendish-square, London, W.

13, Upper Wimpole-street, W.—

To be Sold (with possession) on Tuesday, April 26th, 1887, at the Mart, Tokenhouse-yard, E.C., at 2 o'clock.—For particulars, see THE LANCET, March 26th; or apply to Messrs. Fred. Long & Son, Auctioneers, 4, Adelaide-place, E.C.

South Devon.—To be Let, one mile

from Newton Abbot, six from Torquay, a nicely furnished Country HOUSE. Two sitting, seven bedrooms, very good kitchens, stabling for two horses, large kitchen garden, two orchards. For twelve months from May, £5 per week.—Apply, Mrs. Melland, Westwoods, Newton Abbot.

Wanted, a Country Practice of over

£500 per annum, by a middle-aged, experienced practitioner, doubly qualified (St. Bart.'s). Good house and garden required. Purchaser has ample means.—Apply, Mr. G. B. Stocker, Managing Director, Medical, &c., Assn., Ld., 8, Lancaster-place, Strand, W.C.

Wanted, an unopposed Country

PRACTICE, about £500 per annum, Midlands or west of England preferred. A good residential neighbourhood and detached house, with stabling, large garden, &c., will be of the first importance. Doubly qualified, married, and will pay the market value for a Practice, which must bear full investigation. An early arrangement desired.—Address, G. B. D., THE LANCET Office, 423, Strand, W.C.

Practice or Partnership wanted. —

Mr. Percival Turner has at present an unusual number of applications on his register for good genuine PRACTICES and PARTNERSHIPS in almost any part of England, and he will be happy to hear from Practitioners contemplating retirement or the assistance of a suitable Partner. All negotiations are conducted privately, and no expense incurred unless business done. The full value can in all cases be secured for vendors.—Address, 4, Adam-street, Adelphi, London, W.C.

Yorkshire.—Wanted, an active, experi-

enced, doubly qualified man, competent to take sole charge (Physician, Surgeon, and L.M. preferred). No horse kept, but very easy place. No Club or Poor-law work. State age, height, weight, what experience, and where gained. Salary required in- or out-, and enclose photo. Should above not be engaged, a sober, active, experienced, unqualified man might answer. Can only give very small salary, so that it is most suitable to a man seeking a very easy and comfortable place.—Address, L. M., THE LANCET Office, 423, Strand, W.C.

Eastern Counties.—For Disposal, a

well-established General PRACTICE, in a small country town on a line of rail. Income £600 a year, and good prospects of increase. One horse sufficient. Midwifery from 21s. Good house, with eight bedrooms, garden, orchard, &c. Pleasant residential district. Ill-health the sole cause of leaving. Premium £500, with an efficient introduction.—Address, East, THE LANCET Office, 423, Strand, W.C.

For Transfer, an increasing mixed

PRACTICE. Average yearly income for the last three years £130, including appointments. Is in a good and large thriving Midland town. Equal share of income during introduction, lasting according to purchaser's wishes. Expenses light, and appointments not transferred deducted from premium, which is moderate.—Address, Alpha, THE LANCET Office, 423, Strand, W.C.

Old-established Practices in a Country

Town in South Wales. £360 per annum. Appointments £100, Union. Premium £200, by instalments. One pony. Hunting, shooting, fishing, &c. Knowledge of Welsh not at all required. Every investigation. Choice of capital houses from £25 per annum. Leaving for better facilities of education.—Address, Lex, THE LANCET Office, 423, Strand, W.C.

Digitized by Google

Partnership.—A doubly qualified, registered practitioner desires to meet with a suitable Country Partnership or Introduction where the present holder contemplates retirement. Practice must bear the strictest investigation, so that worthless ones need not be offered. No agents.—Address, with full particulars, in confidence, Medicus, 7, Gower-street, W.C.

Partnership in a small Practice (capable of great immediate development by anyone of energetic disposition) in a populous town, within thirty minutes by rail from London. Price £100 to a good worker. Income guaranteed.—Address, M.D., care of H. Ayres, Esq., Dentist, 11, Princes-street, Cavendish-square, W.

Wanted, by a M.B., C.M. Edin., an ASSISTANTSHIP, with a view to early Succession, in an easily worked Country Practice, returning about £500 per annum.—Address, Trocar, THE LANCET Office, 423, Strand, W.C.

The British and Colonial Agency (Limited) are requested to secure for one of their clients a bonâ-fide PARTNERSHIP, preferably in the country, where from £300 to £500 can be paid down at once, and the rest by annual instalments. He is thoroughly qualified, and well up in his profession. Replies will be treated in the strictest confidence.—Address, The Secretary, 27, Margaret-street, Cavendish-square, London, W.

An Excellent Opening.—A Gentleman is obliged to relinquish a place which he is fitting up as a DISPENSARY in one of the most central parts of London. An active man could make an immediate lucrative practice there. Should be seen at once. Fixtures £30.—Call at 309, Holloway-road, N., before 12.

A Physician and Surgeon, wishing to go abroad, would sell his PRACTICE for £50. Books can be inspected. Receipts realise £3 per week. A rare opening for a young man.—Address, M.D., THE LANCET Office, 423, Strand, W.C.

Wanted, by experienced, fully qualified, married Churchman, an unopposed Country PRACTICE, about £450 (with at least £120 appointments), and scope. Dry climate indispensable.—Send fullest particulars (to save time) to M.B., 7, Arbutus-place, Dublin.

Wanted to Purchase, a small Practice, or SHARE (increasing) in a Practice, in or near London (North), by a fully qualified man willing to work. Premium must be small.—Address, J. Harold, Post-office, Enfield.

London Suburb.—Good Opening for PRACTICE in a rising neighbourhood in the S.W. district. Small premium required. An introduction can be given to a few good patients.—Address, Statim, THE LANCET Office, 423, Strand, W.C.

For immediate Disposal, a good Nucleus, with first-class opening, in a small market town in Midlands. A nominal sum of £50 will be taken, as vendor must leave in three weeks. Furniture at valuation. Reasons given for leaving.—Please address, Immediate, THE LANCET Office, 423, Strand, W.C.

For immediate Disposal, a select and easily worked PRACTICE in the best part of a popular county. Cash receipts over £600 a year. An excellent detached residence, with garden, orchard, stabling, &c., on lease at a low rent. Premium moderate.—Address, R. H., 21, Stowe-road, Shepherd's-bush, London, W.

To be Sold immediately, Vendor having accepted an appointment, a thoroughly genuine Cash PRACTICE, situate in an aristocratic neighbourhood, and can be increased to any amount. It is requested that only those with means at command and who intend business will apply. Would suit a young man well.—Address, J. W. Q., THE LANCET Office, 423, Strand, W.C.

A Branch Practice for Disposal in one of the Midland Counties. On line of rail. An hour from London. Receipts over £200. £50 transferable. A good opening for young man. Easy terms.—Address, Salus, THE LANCET Office, 423, Strand, W.C.

Chemist's Retail, old-established, nicely fitted and stocked. Returns for twenty years average from £500 to £600 when managed by principal. Under assistant they have dropped, but surgeon could make a return of £800. Cause of sale, proprietor unable to attend to it. Price £255.—Address, Chemicus, THE LANCET Office, 423, Strand, W.C.

The British and Colonial Agency, Limited, 27, Margaret-street, Cavendish-square, London, W., are instructed to Dispose of a PRACTICE (1040) situate in a large town in Kent. Receipts about £350. It is an excellent opportunity for a man desiring scope and small working expenses. Less than a year's purchase will be taken.

Small Country Practice for Sale. Pleasant house, good gardens, stable, &c. Very slight opposition. Shooting, hunting, and fishing. Easy access to several large towns. To a doubly qualified married man of good address, able to enter at once, terms would be offered which would prove the investment bonâ fide.—Address, N. O. G. E., THE LANCET Office, 423, Strand, London.

For immediate Disposal, a small Practice in S.E. Suburb, returning over £200 per annum, chiefly cash. Small premium. Introduction if required. Satisfactory reasons for leaving. Populous neighbourhood.—Particulars of Messrs. Hewlett & Son, Druggists, Charlotte-street, Great Eastern-street, E.C.

Wanted, a Practice, by a M.D., M.R.C.S. (South of England preferred); or a Nucleus entertained. Means at command. No agents.—Apply, M.D., care of F. G. Cooper, Esq., 4, Waterloo-place, Pall-mall, London.

Cash Practice for Sale, doing £6 per week. North of England. Will accept £200, on easy terms. Vendor leaving for health.—Address, W. G., THE LANCET Office, 423, Strand, W.C.

Immediate.—£300 a year.—Six years established. Nice class PRACTICE in large Midland town. Small house, well situated, £250 cash. No agents. Full particulars on application.—Address, A. D. M., THE LANCET Office, 423, Strand, W.C.

A Surgeon would be glad to pay a good premium for satisfactory information respecting a good opening for PRACTICE, or would act in conjunction with an elderly practitioner.—Address, Surgeon, THE LANCET Office, 423, Strand, W.C.

£100.—Incumbent, having obtained appointment, will dispose of old-established, ready-money PRACTICE in S.E. district to prompt purchaser.—Address, H. S., THE LANCET Office, 423, Strand, W.C.

Out-door Assistancy or Management of Branch, by an M.D., M.Ch., and L.M. Of large experience. Good references. Married. Disengaged at present.—Address, K., 16, Hawley-crescent, Camden-town, N.W.

Assistants and Locum Tenens supplied on the shortest notice. Apply to Mr. G. B. Stocker, Secretary, Medical, &c., Assn., Ld., 8, Lancaster-place, Strand, W.C. The rule of the Association is that no Assistant shall be recommended till direct inquiries have been made as to his antecedents. Names of the Committee of Management and descriptive pamphlet on application.—Telegraphic address, "Triform, London."

Locum Tenens.—Wanted, a re-engage- ment by M.R.C.S., L.R.C.P.Lond. Age thirty-four. Thoroughly reliable and experienced.—Address, H. B., THE LANCET Office, 423, Strand, W.C.

Locum Tenency wanted by a Gentle- man, doubly qualified. Extensive experience in all kinds of Practice. At present doing locum. Aged thirty. Average height and weight. Good horseman. High-class references. Disengaged May 1st. Address, Medicus, care of John Gill, Esq., Welshpool.

Locum, or in-door Assistancy, desired by a qualified and registered gentleman, R.C. Practical experience in all branches. Dispensary, Club, Union, and General Practice. Good Accoucheur. Can ride and drive. Excellent references.—Address, Jack, 85, Pimlico-road, Belgravia, S.W.

Locum Tenency required by a regis- tered English gentleman, used to every class of Practice. Sober, hard-working, well up in his work, and exceptionally well received by patients. Capital references. Terms, five guineas a week and expenses. Would suit those preferring to pay well and leave Practice in safe keeping.—Address, Practical, THE LANCET Office, 423, Strand, W.C.

Locum Tenens.—A doubly-qualified Medical Gentleman (registered), now disengaged, seeks an Appointment in town or country. Has frequently acted in sole charge, and is accustomed to all kinds of practice—Private, Club, and Union. Satisfactory recent references and testimonials. Can ride and drive.—Telegrams or letters to Medicus, Rutland House, 101, Sackville-road, Hove, Brighton.

Locum Tenency or Assistantship (out- door), or to Manage a Branch, wanted immediately in London, or near, by a doubly-qualified gentleman, M.R.C.S. Eng., L.R.C.P. Lond. (Bart.'s). Two years' experience since qualifying in town and country practice. Late house-surgeon to Western London Public Dispensary. Recent excellent testimonials, thoroughly reliable. Abstainer; not afraid of work. Age twenty-seven; height 6 ft. Would not object to Liverpool, Manchester, Leeds, Dublin, or other large town. Very moderate salary required, as little time for hospital is required.—Address, Dr. D., THE LANCET Office, 423, Strand, W.C.

Qualified Assistants wanted (1) London, S.W., temporary engagement, £10 a month, in-door. (2) Essex, single, £140, out-. (3) Essex, out-door, for May and June. (4) Wales, £100, rooms and attendance. (5) Sussex, country town, £80, in-door. (6) London, Branch Surgery, salary by commission, with fixed minimum, rooms, &c. (7) Lancs., for Branch Dispensary.

UNQUALIFIED ASSISTANTS wanted (8) Lincs., £52, in-. (9) London, N.W., £100, out-. (10) Lancs., £40, in-. (11) Yorks., town, out-door. (12) Birmingham, £75, with unfurnished rooms and gas. (13) Staffs., high-class Practice, £40 to £55, in-door.

The Committee have a constant succession of Assistancies to offer, and invite applications for the same to the Managing Director, Mr. G. B. Stocker, Medical, &c., Assn., Ld., 8, Lancaster-place, Strand, W.C.

Allen & Hanburys'

INFANTS' FOOD.

SPECIAL NOTICE.—THE MALTED FARINACEOUS FOOD (Patented) manufactured by ALLEN & HANBURYS, is the result of a PRACTICAL application of the advice of LIEBIG, and the benefits accruing from its use verify in a remarkable manner his predictions of the value and efficacy of such a Food.

It is PARTIALLY predigested, having as a basis a carefully cooked wheaten flour, especially rich in gluten, to which are added the active and nutritive constituents of pure malt IN A SOLUBLE FORM. It thus contains all that is VALUABLE in Malt, whilst all that is irritating and indigestible is rejected.

When this Food is prepared for use, by mixing with warm milk or milk-and-water, as indicated in the directions, the diastasic action on the already broken starch granules is very rapid, whilst the milk is prevented from forming indigestible curds in the stomach, partly by the mechanical action of the Malted Food, as described in a leading article in THE LANCET of Nov. 20th, 1886, and partly by the power of Malt Extract to prevent the aggregation of the caseine.

This Food is not so entirely predigested as to leave nothing for the infant's stomach to perform, and it is believed that the excellent practical results obtained are largely due to the special proportion maintained between the predigested and the unaltered portions.

NOTE.—Where Medical Men have an opportunity of making comparative experiments with this Food as in crèches, children's hospitals, &c., ALLEN & HANBURYS will gladly supply a reasonable quantity for such purposes, free of charge.

Sold only in Tins, at 6d., 1s., 2s., 5s., and 10s. each.

MANUFACTURED BY

ALLEN & HANBURYS, Plough Court, Lombard Street, LONDON.

PRINTED by BALLANTYNE, HANSON, & Co., No. 4, Chandos-street, in the Parish of St. Paul, Covent-garden, Westminster, in the County of Middlesex, and published by JOHN JAMES CROSS, of No. [illegible] Strand, in the Parish of St. Martin-in-the-Fields, Westminster, in the said County, at No. 48, Strand aforesaid; and sold by all Booksellers and Newsmen in Great Britain and Ireland and the Colonies.—Saturday, April 16, 1887.
